Introduction to Guidewire Configuration

NEXT >

Fundamental areas of configuration

The three-tiers are the three fundamental areas of configuration.

There is also a fourth area of configuration for the development of integration points to external systems. Each application is typically integrated with a number of external systems. The connections to these systems are configured through the application APIs.

Typical examples:

- Policy Administration System
- Billing System
- Claim System
- Authentication (LDAP / Active directory)
- Document storage
- Document production
- Address Book (Contact management system)
- Printing System, etc....

Integration topics are discussed in Integration courses.

Fundamental areas of configuration

Database

Application Server

User Interface

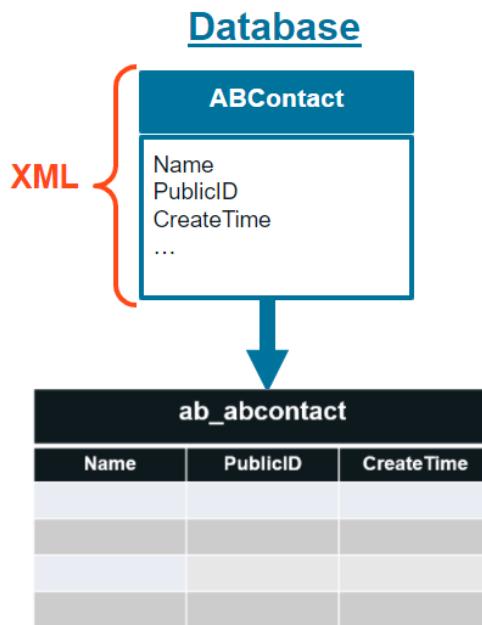

Data model entities

A data model entity is a high-level business object used by the Guidewire application, such as ABContact, Policy, Account, Invoice, Claim. It defines the information about the object that must be stored in the database, such as Name, PublicID, and CreateTime. It is defined in a set of one or more XML files.

In most cases, each data model entity corresponds to a table in the database. The data model entity definition defines the table structure. The fields of the entity will become columns in the database table. Each instance of the data model entity is stored as one row in the database table.

In development environments, when the application server gets restarted or the application gets re-deployed, the database will be automatically upgraded based on the data model.

Page 10

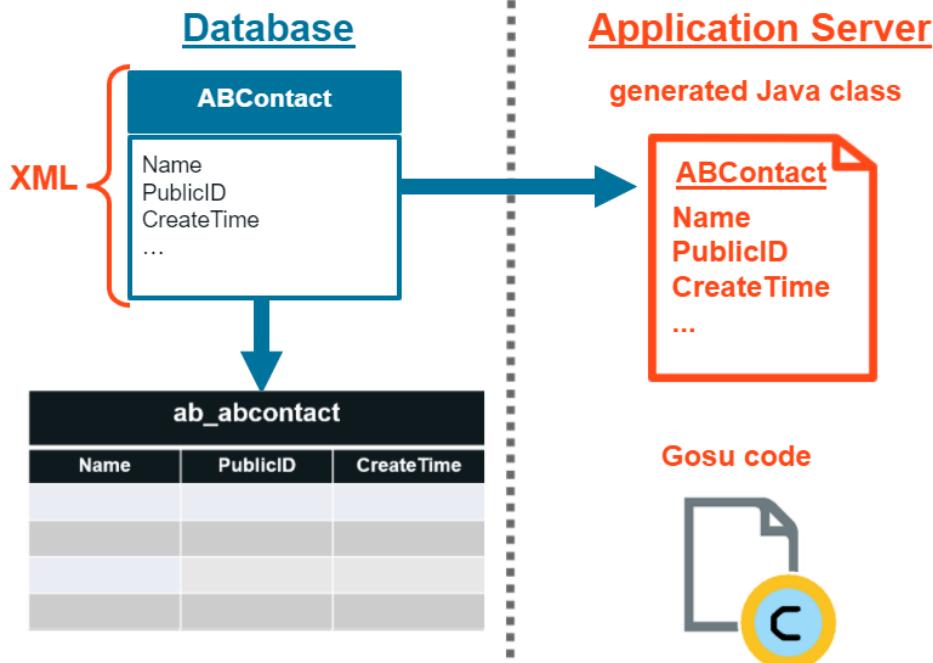

Gosu and generated Java classes

For every data model entity, there is a generated Java class with the same name. For every field in the data model entity, there is a field in the corresponding generated Java class. For example, the ABContact data model entity has a "Name" field, and the generated ABContact Java class also has a "Name" field. In InsuranceSuite, Guidewire Studio makes the process of code generation explicit and the generated code itself accessible. The generated Java class can be viewed and debugged in Studio.

Whenever the application needs to work with an instance of a data model entity (which is stored as a row in the corresponding database table), the application creates an instance of the corresponding Java class. The information from the database is then read into that instance. For example, if a user searches for the ABContact whose name is "Express Auto", then the application finds the row in the database table for ABContact, creates an instance of the ABContact Java class, and reads the data from that row into that instance.

The Application Server tier also contains Gosu resources, such Gosu classes, Gosu Rules, enhancements.

Gosu and generated Java classes

Page 11

PCF files (Page Configuration Format)

A PCF file (Page Configuration Format) is an abstract definition of a form or location used by the user interface tier. For example, "ABContactSummaryDV" detail view is used to display information about an ABContact. It defines the information about the objects to be displayed in the user interface, such as the Name, Public ID, Created On and Assigned User fields. It is defined in a set of one or more XML files using the proprietary PCF XML schema definition.

There is a strong correspondence between data model entities and generated Java classes. Every data model entity has one generated Java class. There isn't necessarily a strong correspondence between generated Java classes and PCFs. The data for one Java class could be displayed in a single PCF, or it could be displayed across multiple PCFs. The separation of the user interface tier and the application server tier gives developers the freedom to display data in whatever way makes sense to end users without being constrained by how that data is maintained in the application server or how the data is stored in the database.

PCF files (Page Configuration Format)

Components working together – displaying Express Auto (1 of 6)

In this example we can see how the system uses the different components to display data from the database.

The user clicks a button in the user interface to display the details of Express Auto. TrainingApp performs the steps described on the following slides.

The Guidewire platform

The Guidewire platform is layer of configuration technology that includes the functionality needed to define a Guidewire applications. For example, it includes:

- The technology to define a data model
- The technology to define a user interface
- The technology to define application logic
- The technology to define integration points

Every application uses this common technology to define its own data model, user interface, business logic, and integration points. Each application is distinct, but every application shares common features and configuration techniques with all the other applications. For example, users can be created, modified or deleted the same way by the administrator in all the Guidewire applications. That is why data model entities, PCF files and application logic to manage Users are defined in the platform.

The Guidewire platform

- The Guidewire platform is a layer of configuration technology that includes the functionality needed to define a Guidewire application
- It contains common resources and configuration techniques that are shared by all Guidewire applications. For example:
 - Data model entities, PCF files, and application logic to manage Users
 - Data model entities and PCF files to create and assign Activities to other users
 - This course focuses on the Guidewire platform

Guidewire Platform offers technology for configuring...

Application-specific functionality

Each application also has application-specific functionality.

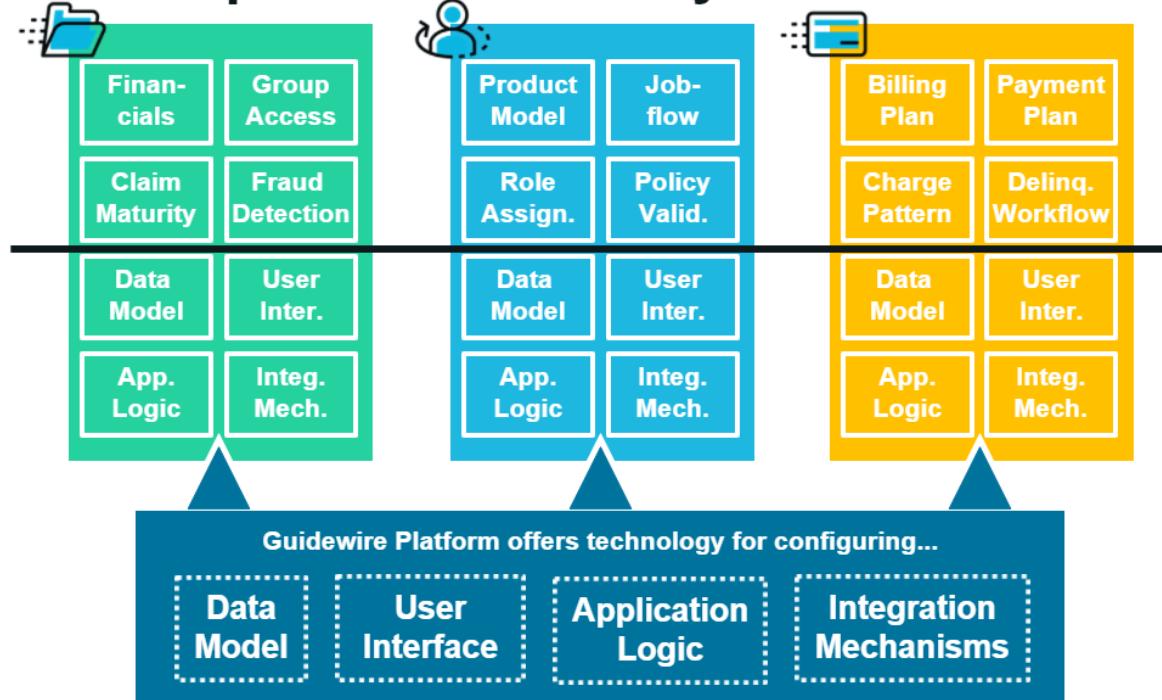

The PolicyCenter-specific functionality includes:

- The product model, which defines products, the policy lines assigned to each product, the coverages and coverables for the product, and the coverage terms for those coverages.
- Job flow, which defines how policy transactions (such as submissions, renewals, changes, and cancellations) are executed.
- Role assignment, which defines how users are assigned responsibility for a given account, policy, or policy transaction.
- Policy validation, which validates that a given policy is valid, quotable, bindable, or issuable.

The BillingCenter-specific functionality includes:

- The management of invoices over the billing cycle from planned to billed to due.
- The production of producer commission statements for business collected directly from the client and the production

What is the data model?

A set of XML-formatted metadata definitions of entities and typelists

The core data structure for all Guidewire applications

Loaded on start-up of all Guidewire applications

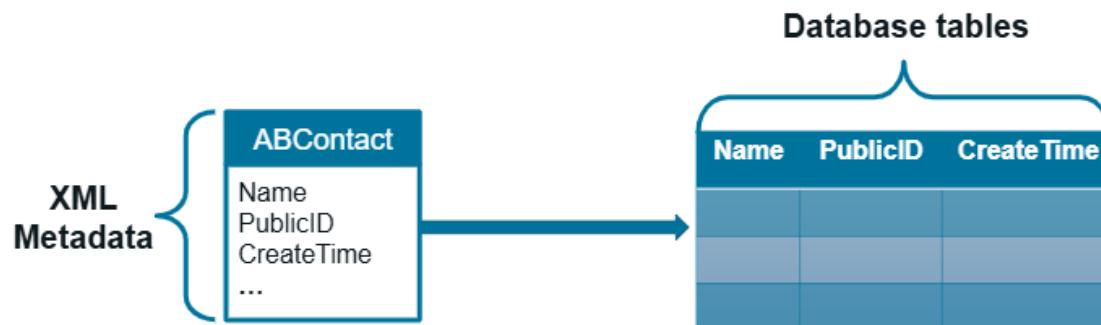

The Guidewire data model and the database

As part of the application start-up, the loaded metadata instantiates the data model as a collection of tables in the application database. Entities defined in the data model map to tables in the database and fields map to database columns, except for arrays and virtual properties.

The Guidewire data model and the database

The metadata instantiates a collection of tables in the application database

Guidewire applications employ a metadata approach to data objects. A Guidewire application uses the metadata about application domain objects to provide generated Gosu and Java interfaces to these objects. Those Java and Gosu classes provide programmatic access to the data objects defined in the data model.

The Guidewire data model and classes

Injects generated Java and Gosu classes in the application server for programmatic interfaces to entities and typelists

Page 7

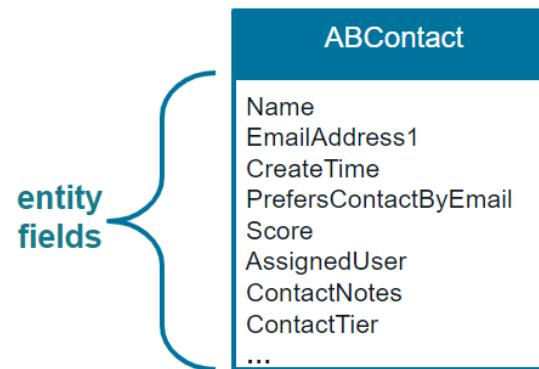

Data fields

Data fields are defined in XML for an entity file with a <column> element. Therefore, they are sometimes referred to as "column fields". There are other types of fields beyond primitive value fields that are stored in database table columns, however. So one should not assume that the only fields that map to database columns are the "column fields". This course uses the term "data fields" to avoid this possible point of confusion.

Data fields

- A data field stores a single value that does not reference any other object or table
- Typically defined with the <column> element
- Examples of single values:
 - Name is a varchar
 - CreateTime is a datetime
 - PrefersContactByEmail is a bit
 - Score is an integer

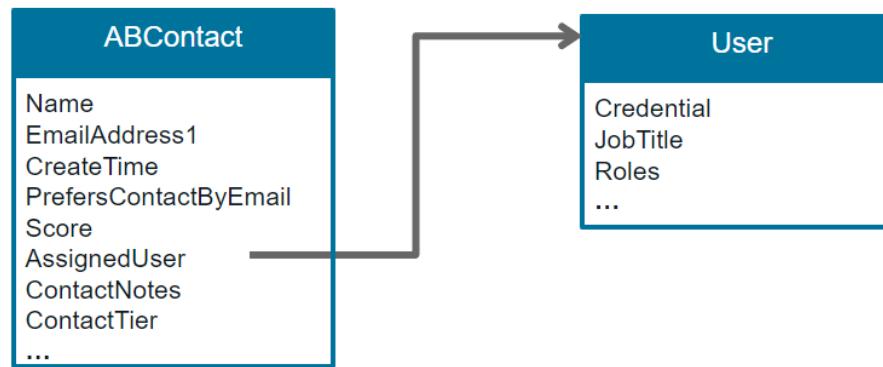

Foreign key fields

Note: At its simplest, the Guidewire data model is a set of XML-formatted metadata definitions of entities and typelists. An entity defines a set of fields for information. You can add a Foreign Key field to an entity.

Foreign key fields

- A foreign key field stores a reference to a related object in the Data Model
- It defines a unidirectional relationship
- AssignedUser in ABContact is the foreign key field for a User

How to define an Array relationship between two Entities A and B ?

Notes

Array fields

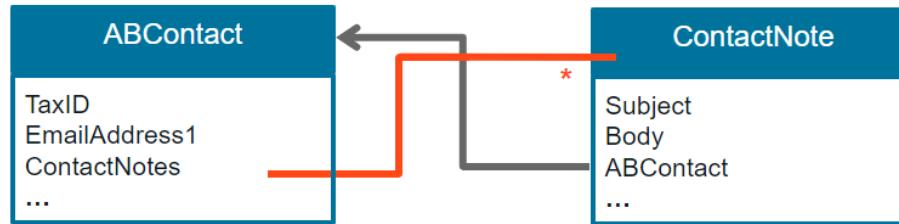

Note: At its simplest, the Guidewire data model is a set of XML-formatted metadata definitions of entities and typelists. An entity defines a set of fields for information. You can add an Array field to an entity.

Menu

Array fields

- An array defines a set of additional entities of the same type to associate with the main entity
- For example, ABContact entity includes an array of ContactNote entities. This means ABContact can have zero, one or more ContactNotes associated to it.

Page 8

[◀ PREV](#) [NEXT ▶](#)

What is Typelist and what entity property we use to save in the Entity ?

Notes

Typelists and typekey fields

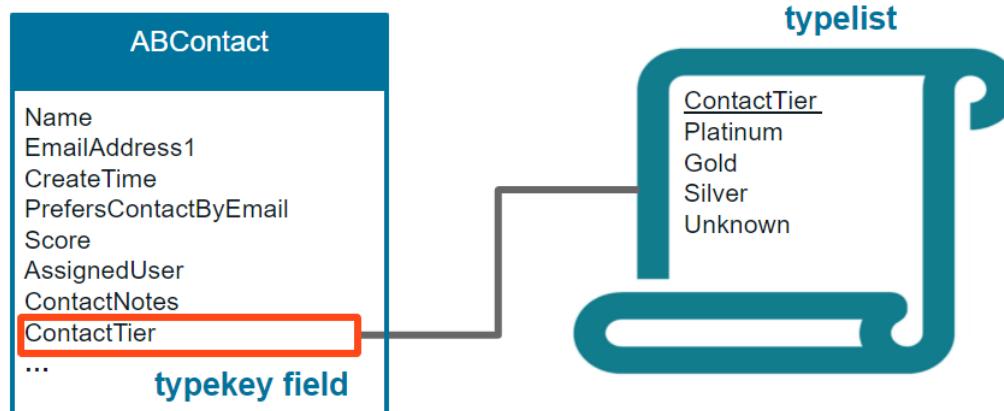

Note: At its simplest, the Guidewire data model is a set of XML-formatted metadata definitions of entities and typelists. An entity defines a set of fields for information. You can add a Typekey field to an entity.

Menu

Typelists and typekey fields

- A typelist is a predefined set of possible values that limits the acceptable values for fields within the application. In most cases a typelist is rendered as a drop-down list in the user interface
- A typekey field is entity field that is associated with a specific typelist. It can point to exactly one value in the typelist

Page 9

[◀ PREV](#) [NEXT ▶](#)

Supertype (subtyped) entities

Subtype entities are children entities of a top level supertype (parent) entity. All fields in the parent entity are inherited by the child entity.

ABContact is a top level supertype entity. The ABContact entity is an abstract entity (abstract=true). Abstract entities cannot be instantiated, but they can be subtyped. In other words, this means that you cannot create instances of an ABContact, but you can create entity instances of its subtypes such as instances of ABPerson, ABCompany, ABPersonVendor, ABPolicyPerson, ABAdjudicator, ABAttorney, and ABDocket.

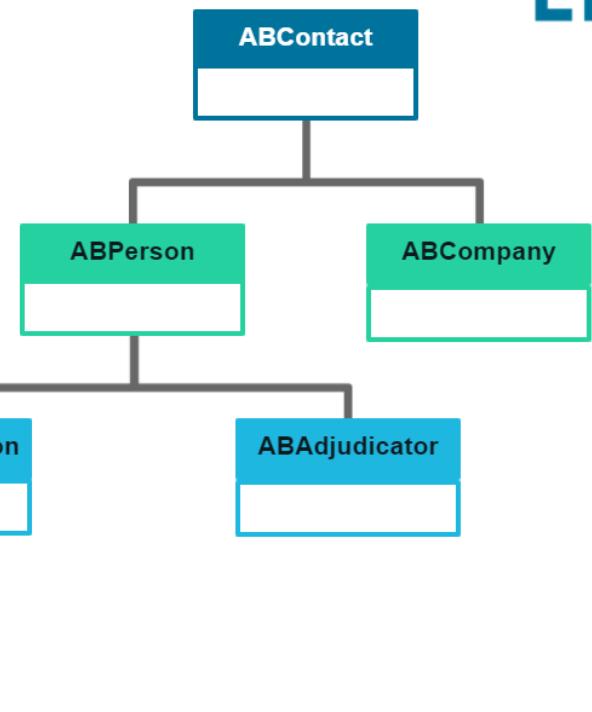

Not all top level supertype entities are abstract. It is also possible to have subtype entities that are abstract.

Another way to describe a supertype entity is to use the term "subtyped" entity. In the slide example, there are several subtyped entities including ABContact, ABPerson, and ABPersonVendor. The slide diagram does not reflect all the supertype and subtype entities in TrainingApp.

Supertype entities in ClaimCenter include Contact, Incident, and Transaction. Contact and Transaction are abstract entities.

Supertype (subtyped) entities

- If multiple entities have a common set of fields then they could be organized into a hierarchy
- The entities in the same hierarchy will use the concept of inheritance
- This means that fields and methods of supertype entities are inherited by subtype entities

Guidewire Proprietary & Confidential – DO NOT DISTRIBUTE
© 2021 Guidewire Software, Inc. For information about Guidewire's trademarks, visit <https://www.guidewire.com/legal-notices>.

Page 10

How does Entity gets saved in the underlying database ?

Notes

Entities in the database

There are two exceptions to the generalization above: virtual and subtype entities.

Virtual, Non-persistent entities are entities constructed entirely with code. They exist during runtime, and when the Guidewire application shuts down, the data is not saved to the database. An example of a non-persistent entity is ABContactSearchCriteria in TrainingApp. Guidewire recommends that you do not create non-persistent entities as a general rule.

Subtype entities are entities that are children entities of a top level supertype (parent) entity. All fields in the parent entity are inherited by the child entity. A top level supertype entity and all of its child subtypes are stored in a single database table. In this manner, all the entities share the same database table.

Entities in the database

Table - dbo.ab_abcontact*

ID	Name	CreateTime	PrefersContact...	Score	AssignedUser
64	United Natural Foods Inc	9/4/2009 1:51:32 PM	False	NULL	2
65	3M	9/4/2009 1:51:32 PM	False	NULL	3
74	Express Auto	9/4/2009 1:51:32 PM	False	81	3
75	European Autoworks	9/4/2009 1:51:32 PM	True	NULL	4
76	M B Garage	9/4/2009 1:51:32 PM	False	NULL	7

Page 13

[PREV](#) [NEXT](#)

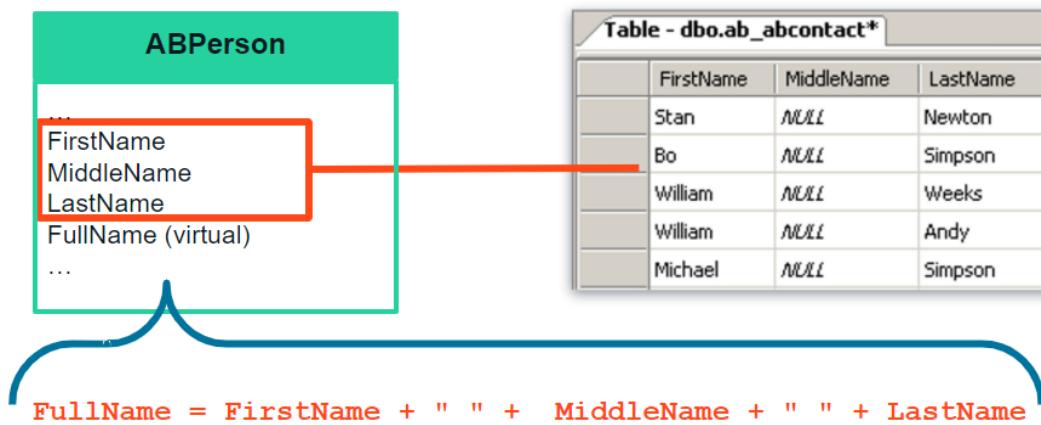

Data fields in the database

In the example above, the FullName field is a virtual field or property. FullName concatenates the values of the FirstName, MiddleName, and LastName physical fields. Virtual fields are defined as Gosu code in Enhancements. Entity Enhancements are discussed in another lesson.

Data fields in the database

- Data fields can be physical or virtual
 - Data model defines physical fields as columns in a database table
 - Gosu code defines virtual fields and there is no physical database column

Foreign key connected PK of one table to FK for another table

Notes

Menu

Foreign key fields in the database

In the slide example, the assigned user (4) for European Autoworks is Alice Applegate. The assigned user (3) for 3M and Express Auto is System User. The assigned user (2) for United Natural Foods Inc is Super User.

Foreign key fields in the database

- Foreign key fields are stored as foreign key columns

	ID	FirstName	LastName
▶	1	Default	Owner
	2	Super	User
	3	System	User
	4	Alice	Applegate

Table - dbo.ab_abcontact*			
	ID	Name	AssignedUser
	64	United Natural Foods Inc	2
	65	3M	3
	74	Express Auto	3
	75	European Autoworks	4

Page 15

◀ PREV NEXT ▶

In Arrays – We create array from one Entity and reverse Foreign key from other Entity

Notes

Array fields in the database

Array keys are managed during run-time by code that queries the database for objects of a given type with foreign keys that point to the array's parent.

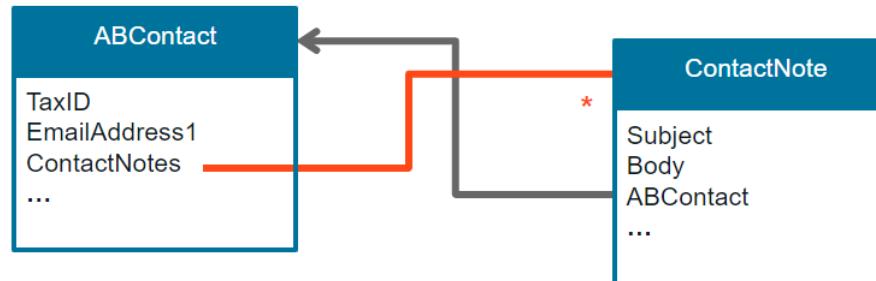

For example, assume you have an ABContact object named ericAndy that stores the ABContact data for Eric Andy. Whenever you reference ericAndy.ContactNotes, Guidewire queries the database for all ContactNote objects whose ABContact field points to Eric Andy and returns those objects in an array.

Menu

Array fields in the database

- Arrays are not stored in the database, but populated at runtime by queries
- Every array on the main entity must have a reverse foreign key pair on the associated additional entity

Guidewire Proprietary & Confidential – DO NOT DISTRIBUTE

Page 17

How does Subtype gets saved in the database ?

how to retrieve subtype from the database ?

Notes

Menu

Subtype entities in the database

Whenever an entity is subtyped, a virtual typelist is automatically created for it. This typelist contains one typecode for every subtype of the parent entity. Typelist tables are prefixed with "xxtl_ ", where "xx" is the two-letter application code.

The ab_abcontact table is the parent or supertype table that stores all instances of ABContact and its subtypes.

Subtype entities in the database

- Supertype parent table stores all instance of itself AND of subtype data
 - Contains parent fields and all subtype fields
 - Irrelevant fields are null for specific subtypes
 - Application automatically creates typelist table of all subtypes
 - Subtype column identifies subtype
- Example: FIRSTNAME and LASTNAME are always null for subtype = 3

SELECT ID, TYPECODE FROM ABTL_ABCONTACT	
ID	TYPECODE

Define an Entity ? Any Example

Notes

Entity

At its simplest, the Guidewire data model is a set of XML-formatted metadata definitions of entities and typelists. An entity defines a set of fields for information.

Menu

Entity

object entity

- An entity is a definition of a business object used by the application, such as Policy, User, ABContact, Producer, etc.
- Entities are defined in entity definition files (ETI)
 - The ETI file describes the entity in XML format
 - There are two main types of entities:
 - Base application entities
 - Custom entities

Page 4

◀ PREV NEXT ▶

What are .eti ?

Notes

Base application entities

Platform entities are always found in the ...\\modules\\configuration\\config\\metadata\\entity\\ folder. All ETI files in the \\metadata\\entity\\ are read-only. You cannot edit these files directly in Guidewire Studio and should not edit these files in any other application. Many platform entities have the platform="true" attribute defined in the <entity /> element.

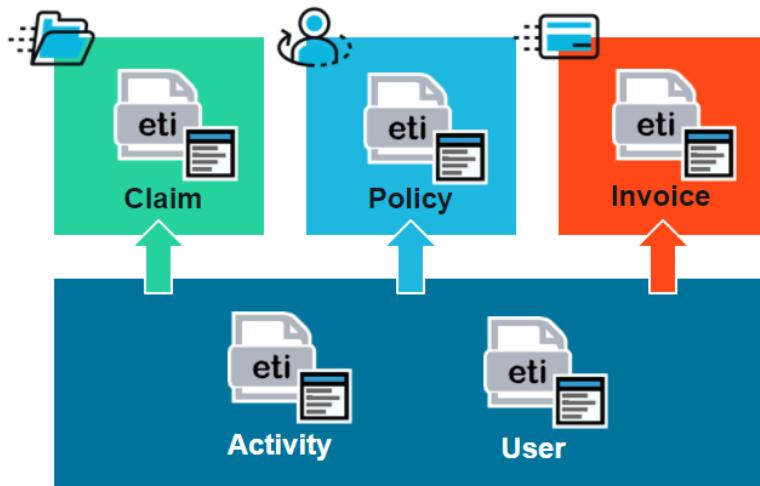

Some application specific entities can also be found in the \\metadata\\entity\\ folder. Many application entities are extendable in the sense that they can be both subtyped and/or an entity extension can be created. Entities with the final="true" attribute defined in the <entity /> element cannot be subtyped. Entities with the extendable="false" attribute defined in the <entity /> element cannot be extended in the sense that new elements cannot be added to the entity.

Menu

Base application entities

- A base application entity is an entity created by Guidewire and shipped as part of the out-of-the-box configuration
- Guidewire creates base application entities on the application or the platform level

- Application entities are specific to application
- Platform entities are common to all Guidewire applications

Guidewire Proprietary & Confidential – DO NOT DISTRIBUTE
© 2021 Guidewire Software, Inc. For information about Guidewire's trademarks, visit <https://www.guidewire.com/legal-notices>.

Page 5

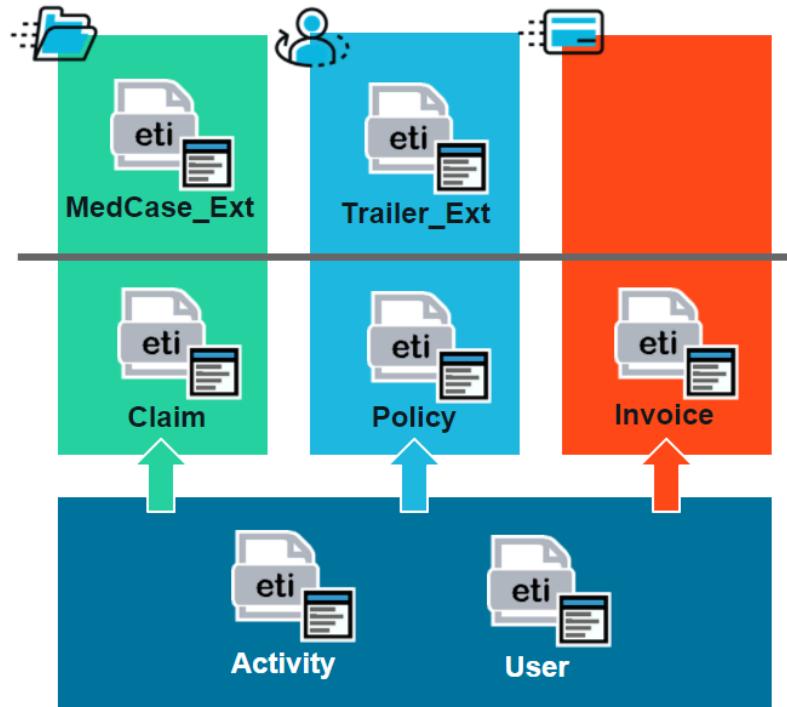

◀ PREV NEXT ▶

Custom entities

Custom entities are always found in the ...\\modules\\configuration\\config\\extensions\\entity\\ folder.

Custom entities

- A custom entity is an entity created by the customer
- A custom entity can be created only on the application level and it will be local inside that application

Guidewire Proprietary & Confidential – DO NOT DISTRIBUTE

© 2021 Guidewire Software, Inc. For information about Guidewire's trademarks, visit <https://www.guidewire.com/legal-notices>.

Page 6

Entity extension

Note: To avoid future naming conflicts when Guidewire adds or changes base entities, Guidewire recommends that you add the suffix _Ext to your entity names and new field names on base entities. Adding the _Ext suffix to entity names results in Studio and the Data Dictionary listing these extensions next to any entities that they extend. For example, CreditHistory_Ext.

If you add a new entity, its field names do not need the _Ext suffix in their names, because you have the _Ext suffix in the name of the entity.

Entity extension

- Base application entities are read-only to prevent any conflicts during upgrade to the next version of the Guidewire application
- The concepts of an Entity extension allows customers to safely add new fields to base application entities or to override certain attributes of existing base application entity fields
- The entity extension is defined in an ETX file
- To keep the maintenance of entities simple a base application entity can have at most one ETX file
- For fields that are added to a base application entity, Guidewire recommends that the field name should end with _Ext

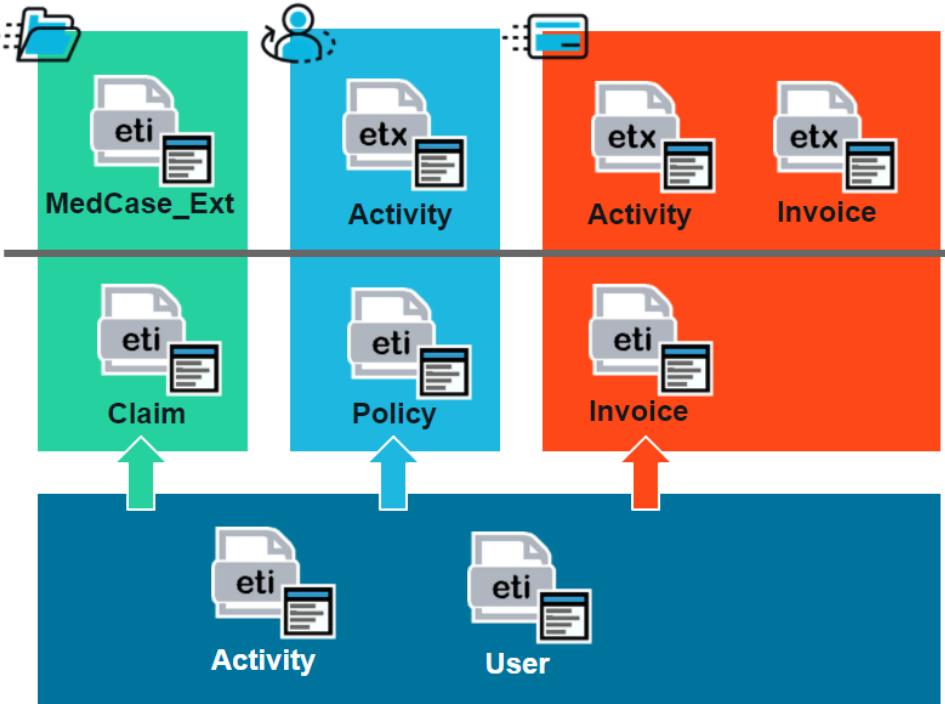

Extending base application entities

Customers can create or edit entity extensions. Entity extensions are always found in the ...\\modules\\configuration\\config\\entity\\extensions\\entity\\ folder.

Guidewire provides certain entity extensions as part of the base application configuration. Many of the extension index definitions address performance issues. Other extensions provide the ability to configure the data model in ways that would not be possible if the extension was part of the base data model. Do not simply overwrite a Guidewire extension with your own extension without understanding the full implications of the change.

Extending base application entities

Page 8

◀ PREV NEXT ▶

What are .etx ?

Notes

Internal Entity Extension

The EIX file contains extensions to the platform-level entities that are required for the base application and cannot be modified. EIX files are extensions to platform-layer entities created by Guidewire development to meet the needs of a given application's base data model.

EIX files are always found in the

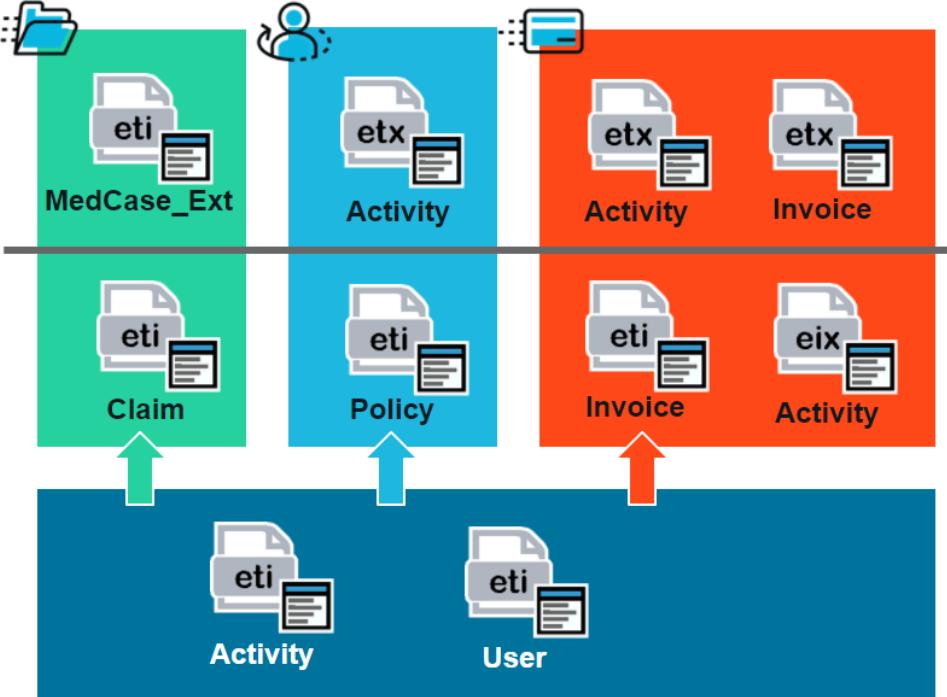

...\\modules\\configuration\\config\\metadata\\entity\\ folder. All ETI and EIX files in the \\metadata\\entity\\ are read-only. You cannot edit these files directly in Guidewire Studio and should not edit these files in any other application.

Because EIX files are neither created nor modified by configuration developers, this lesson does not discuss their structure. If you need to make multiple extensions to a single entity at different points in time, all extensions for that entity should be added to the same ETX file.

Menu

Internal Entity Extension

- An Internal Entity Extension is created by Guidewire to add application specific functionality to a platform level entity
- An EIX file is local in the application and read-only

Best Practices to add a new column in existing entity ?

Notes

Entity extensions and Java classes

For a base application data model entity, the entity is defined by both its original ETI file and the ETX extending file, if one exists. In certain cases, there is an internal entity extension, EIX, file. Regardless of which file the field is declared in, all fields from all files become the generated Java class.

For fields that are added to a base application entity, Guidewire recommends that the field name should end with the suffix _Ext. In the slide example, the ABContact.etx entity extension file contains the WebAddress_Ext field.

Students coming from an Object-Oriented Programming (OOP) background should be aware that the term "extend" gets used in OOP differently than it does in Guidewire. In OOP, the term "extend" is used to refer to creating a new subclass that extends some parent superclass.

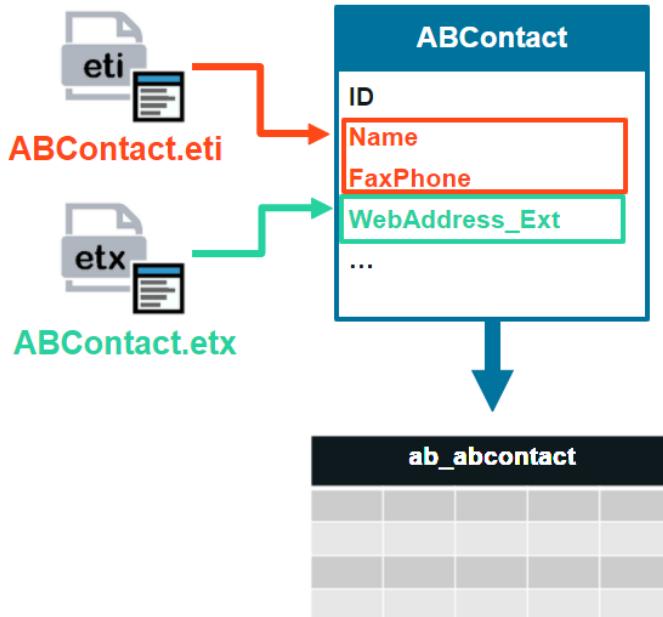

In Guidewire data model configuration, the term "extend" is sometimes used to refer to adding new fields to an existing base application entity. In this sense, no new subclass or subtype entity is getting created. One is simply adding additional fields to an existing base application entity.

What is an Typelist, How do we define one ?

Notes

TypeList

You can programmatically get a list of typekeys in a typelist. You can choose whether to get all typekeys, including retired typekeys as well as non-retired typekeys, or just non-retired typekeys. You can retire a typekey in the data model configuration files. To get typekeys from a typelist, call the getTypeKeys method:
TYPENAME.getTypeKeys(includeRetiredTypekeys)

Menu

TypeList

- A TypeList is a fixed, predefined list of values (Typecodes)
- Values cannot be dynamically added or removed during runtime
- Defined value often used to constrain user input
- When rendered in UI, typically appears as a dropdown list

The screenshot shows a user interface for managing bank accounts. At the top, there are tabs for 'Person Info', 'Phone & Addresses', and 'Bank Accounts'. The 'Bank Accounts' tab is selected. Below the tabs, there is a table with columns: 'Bank Name*', 'Routing Number*', 'Account Number*', and 'Account Type*'. There are three rows of data: one for 'ACME Credit Union' with routing number 123-987 and account number 345678900, and two for 'National Bank' with routing number 745-222 and account number 232323566. An 'Add' button is available to add new accounts.

Below the table, a modal window titled 'BankAccountType.tti' is open. It shows a table with columns: 'Element', 'Code', 'Name', and 'Priority'. A dropdown menu labeled 'typecode' is open, showing options: 'Checking', 'Savings', and 'Other'. The 'typecode' row in the table has a tooltip 'The type ...'. The data in the table is:

Element	Code	Name	Priority
typelist	BankAccountType	The type ...	
typecode	checking	Checking	1
typecode	savings	Savings	2
typecode	other	Other	3

TypeList extension

Filetypes are defined as follows:

.tti - TypeList Type Info, a single Guidewire or custom typeList declaration. The name of the file corresponds to the name of the typeList being declared.

.tix - TypeList Internal extension, a single Guidewire typeList extension. The name of the file corresponds to the name of the Guidewire typeList being extended.

.tx - TypeList Type extension - a single Guidewire or custom typeList extension. The name of the file corresponds to the name.

TypeList extension

- Base application TypeLists are read-only to prevent any conflicts during upgrade to the next version of the Guidewire application
- The concepts of a TypeList extension allows customers to safely add new Typecodes to base application TypeLists
- The TypeList extension is defined in a TTX file
- To keep the maintenance of TypeLists simple a base application TypeList can have at most one TTX file
- For Typecodes that are added to a base application TypeList, Guidewire recommends that the code should end with _Ext

Answer

-- What is the difference between an ETX file and an ETI file?

An ETX file extends a base application entity e.g. adding new columns. An ETI file defines a new custom entity from scratch.

Does the base application have ETI files? Can developers create new ETI files? Where and how? (Answer)

Answer

Does the base application have ETI files? Can developers create new ETI files? Where and how?

Yes, ETI files are in the base application. Developers can create new ETI files in the ...\\extensions\\entity\\ folder using Guidewire Studio and the Entity Editor.

PREV NEXT

Entities, Java classes and database tables

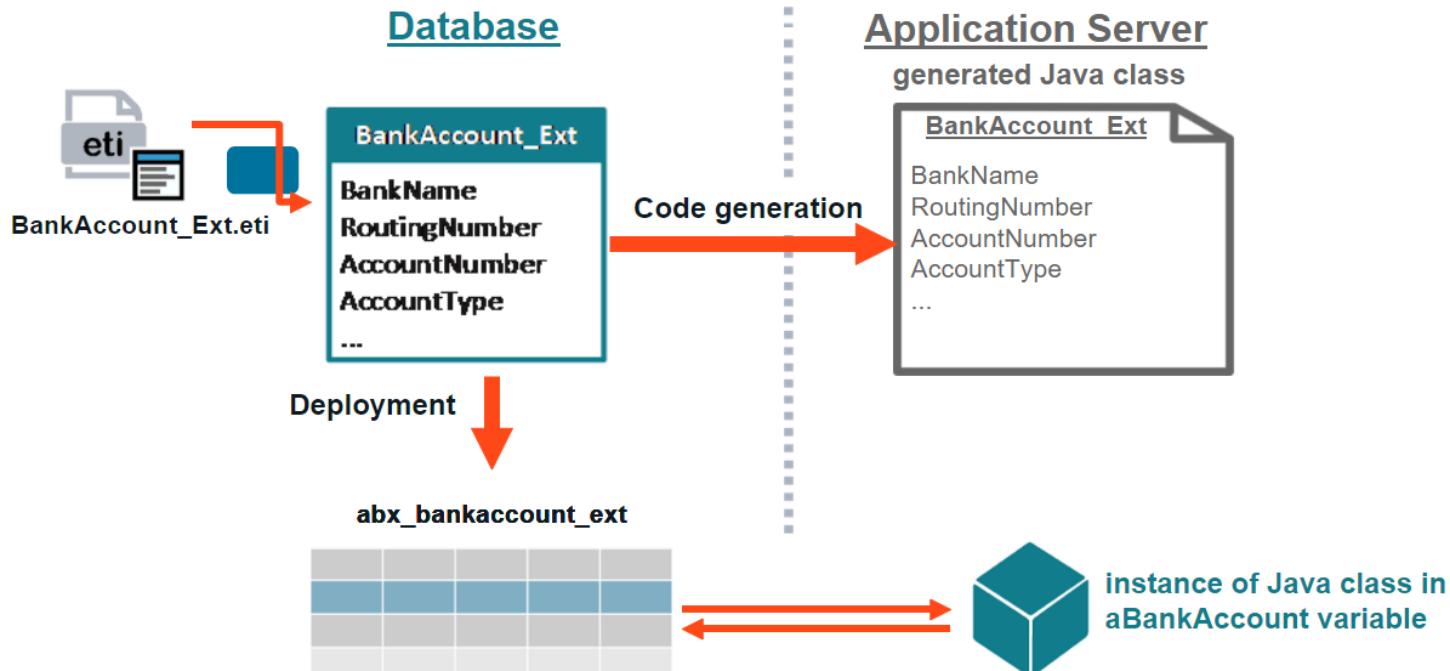

For a customer data model entity, the ETI file defines the fields. Custom entities are a single ETI file that customers can edit as needed. A customer entity will consist of only an ETI file and it cannot have EIX or ETX files. All the fields in the custom entity's ETI file become a part of the generated Java class and a database table.

For custom entities, Guidewire recommends that the entity name should end with _Ext, for example, BankAccount_Ext. The names of the fields in the custom entity do not need to end with the _Ext suffix.

The name of the database table is automatically generated to match the name of the ETI file and is all lowercase, for example, bankaccount_ext. Guidewire creates a special prefix for custom entities by appending x to the two-letter product code for the table name, such as abx_bankaccount_ext. The table name is an attribute of the entity xml element and must have a length of 25 characters or less. When creating an entity, if the entity name has a length of more than 25 characters, you can modify the table name in the Entity dialog to reduce the length to 25 or less, including removing the _ext suffix from the table name.

Entities, Java classes and database tables

Notes

Entities in the database

There are two exceptions to the generalization above: virtual and subtype entities.

Virtual. Non-persistent entities are entities constructed entirely with code. They exist during run-time, and when the Guidewire application shuts down, the data is not saved to the database. An example of a non-persistent entity is ABContactSearchCriteria in TrainingApp. Guidewire recommends that you do not create non-persistent entities as a general rule.

Subtype entities are entities that are children entities of a top level supertype (parent) entity. All fields in the parent entity are inherited by the child entity. A top level supertype entity and all of its child subtypes are stored in a single database table. In this manner, all the entities share the same database table.

Entities in the database

```
select bankname, routingnumber, accountnumber, accounttype from abx_bankaccount_ext;
```

BANKNAME	ROUTINGNUMBER	ACCOUNTNUMBER	ACCOUNTTYPE
ACME Credit Union	123-987	345678900	10001
National Bank	745-222	232323566	10001
ACME Credit Union	123-987	112233445	10001
ACME Credit Union	123-987	554433221	10002

(4 rows, 6 ms)

BankAccount_Ext

BankName
RoutingNumber
AccountNumber
AccountType
...

- Often, an entity stores data in a database table named for the entity:
 - BankAccount_Ext entity in abx_bankaccount_ext table
 - ABContact entity in ab_abcontact table
- Exceptions are...
 - Entities that share the columns in an entity table such as a subtype entity
 - Virtual, non-persistent entities do not save data to the database. Guidewire recommends that you do not create non-persistent entities as a general rule

Page 9

Data relationships

Now let us take a look at the kinds of relationships that exist between data entities in Guidewire applications.

Data relationships

Guidewire Proprietary & Confidential – DO NOT DISTRIBUTE

© 2022 Guidewire Software, Inc. For information about Guidewire's trademarks, visit <https://www.guidewire.com/legal-notices>.

Foreign key

If a foreign key field is added to a base application entity, then the suffix should be _Ext.

For a complete reference of the <foreignkey> syntax, refer to the application's Configuration Guide.

Foreign key

- Pointer to single instance of some other entity
- Example: each Contact can have one assigned user

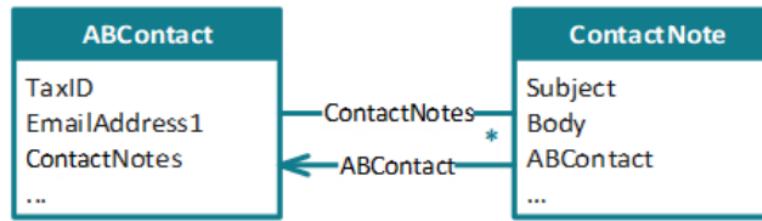

Keep in mind that arrays are maintained in code. The code assembles the array by executing queries against the database. In order to do this, the application must be able to query for all members of a given array. It can do this only if each member has a foreign key referencing its parent. Note that the value of the arrayentity attribute must match exactly the name of the entity it references.

Array

- Collection of pointers to instances of some other entity that is maintained by code during runtime
- Requires reverse foreign key
 - If entity A has array of entity B, then entity B must have foreign key pointing to entity A
- Example: each ABContact can have zero to many contact notes

One-to-one relationships

A one-to-one relationship often splits a logical entity across multiple physical entities. For example, when an ABContact is a ABPolicyPerson or ABPolicyCompany, the data model must capture financial summary information.

Storing the financial summary details into the ABContact table would result in a table with numerous rows with null columns. Instead, it is better to have a separate entity manage the financial summary details. In this manner, every ABContact has (at most) one FinancialSummary, and every financial summary applies to (at most) one ABContact.

For more information on one-to-one relationships, refer to documentation.

One-to-one relationships

- <onetoone> element defines a single-valued association to another entity that has a one-to-one cardinality
- Provides a reverse pointer to an entity that is pointing at the <onetoone> entity through a foreign key
- Often splits logical entity across multiple physical entities
- Example: ABContact defines Financial Summary as one-to-one and FinancialSummary defines a foreign key to ABContact

Many-to-many relationships (1 of 2)

To add a many-to-many relationship between entity types to the data model, first create a separate versionable entity that represents the many-to-many relationship. (Versionable entities have a version and ID field and can be deleted as opposed to retireable entities which can never be deleted). Next, create foreign keys to each entity in the many-to-many relationship. Then add a unique index consisting of the foreign keys in the relationship.

Many-to-many relationships require a separate entity that contains the required foreign keys and a unique index for the foreign key values so that duplicate rows are not added to the table.

Many-to-many relationships (1 of 2)

- Requires an entity of type versionable that represents the many-to-many relationship with the following:
 - Two or more non-nullable foreign keys
 - Unique index for all foreign keys

Many-to-many relationships (2 of 2)

In order to access the many-to-many relationship values, one of the foreign key tables needs to specify an array entity. To access the relationship, add an array to one or both entities in the relationship.

In the slide example, the diagram does not represent the defined relationship in TrainingApp. In TrainingApp, UserRole is of the type joinarray. The joinarray entity type is an internal type and Guidewire does not recommend using this entity type. In addition, only User has a backing Roles array to UserRole.

For more information on many-to-many relationships and entities of type joinarray, refer to the documentation.

Many-to-many relationships (2 of 2)

- To access the many-to-many relationship, add an array to one or both entities in the relationship
 - Roles array in User specifies that there is zero or more UserRoles for a given user
 - Users array in Role specifies that there is zero or more UserRoles for a given role

Circular relationships

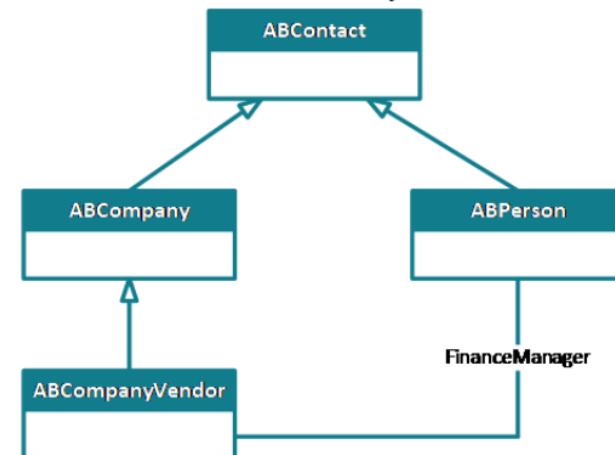

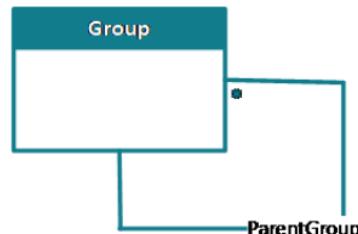

In some cases, an entity needs to refer to itself. This could occur both for a non-subtyped entity (every Group has a parent group) or a subtyped entity when one subtype refers to another (every ABCompany—which is an ABContact—can have a finance manager who is an ABPerson, which is also an ABContact). The Guidewire data model does not let an entity reference itself, or two or more entities reference one another in a cyclical manner, using only foreign keys. This is because Guidewire cannot easily determine the order in which rows can safely be written to the database when a data model cycle exists.

To solve this kind of circular dependency between foreign keys, Guidewire recommends that you use an edge foreign key (`<edgeForeignKey>`). An edge foreign key from A to B introduces a new, hidden entity that has a foreign key to A and a foreign key to B. However, it does not create any direct foreign key from A to B. As such, ClaimCenter can safely commit the A objects first, then the B objects, and finally, the hidden A/B edge foreign key entities. This ensures that the relationship information does not reference non-existent rows. The same principal is true for two or more entities that reference one another in

Circular relationships

- `<edgeForeignKey>` creates an edge table
 - Links one entity to another or to self
 - Ensures the safe ordering of data insertion and deletion in cases where cyclic references prevent safe ordering
- Examples:
 - Child references parent
 - Reference between subtypes

Page 32

◀ PREV NEXT ▶

User Story: Invoicing Method

Shown here is an example user story requirement requested by a fictional business analyst.

User Story: Invoicing Method

"After further analysis, we decided that the invoicing method of each policy also has to be stored in TrainingApp. The invoicing method specifies how the premium will be collected for the policy. An insurance company allows only the following 3 invoicing methods:

- 10% down payment and 11 installments*
- 30% down payment and 4 installments*
- 50% down payment and 2 installments*

We are still working on the UI requirements, so please configure the Data Model only for now."

- Insurance Company Business Analysts

Page 4

[◀ PREV](#) [NEXT ▶](#)

Typelist

Whenever there is a drop-down list in an InsuranceSuite application interface, it is usually a Typelist. If Guidewire defines a typelist as final, it is not possible to add or delete typecodes from the typelist.

Typelist

- A Typelist is a fixed, predefined list of values (Typecodes)
 - Values cannot be dynamically added or removed during runtime
- Defined value often used to constrain user input
 - When rendered in UI, typically appears as a dropdown list

The screenshot illustrates the concept of a Typelist. On the right, a user interface window titled 'Details' shows a dropdown menu for 'Account Type'. The dropdown contains four options: 'Checking', 'Checking' (highlighted in blue), 'Savings', and 'Other'. A red box highlights this dropdown. On the left, a tool window titled 'BankAccountType.tti' displays a table of typecodes. The table has columns: Element, Code, Name, and Priority. It lists three typecodes under the element 'typelist': 'BankAccountType' (Priority 1, Name 'Checking'), 'savings' (Priority 2, Name 'Savings'), and 'other' (Priority 3, Name 'Other'). A red box highlights the entire table, and a red arrow points from the highlighted table to the highlighted dropdown in the UI window.

Element	Code	Name	Priority
typelist	BankAccountType	The type ...	
typecode	checking	Checking	1
typecode	savings	Savings	2
typecode	other	Other	3

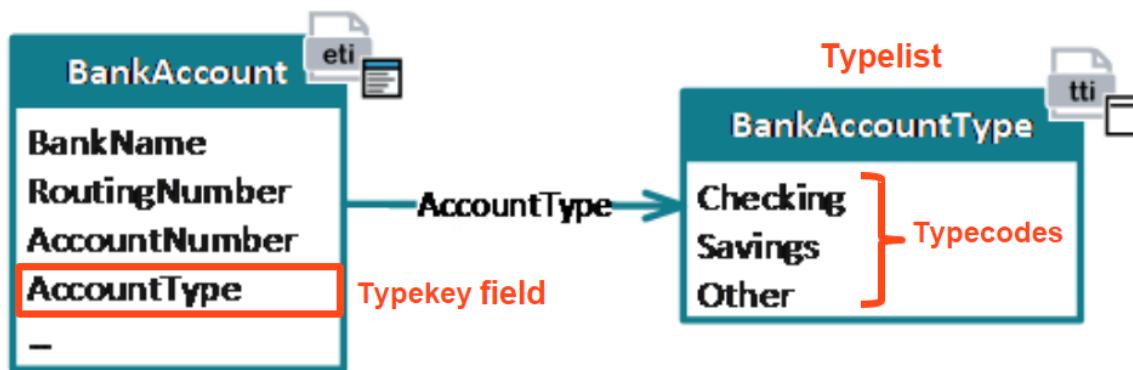

Typelists and Typekey fields

The specified typelist limits the available field values to those defined in the typelist. If you filter the typelist, the field displays a subset of the typelist values.

Typelists and Typekey fields

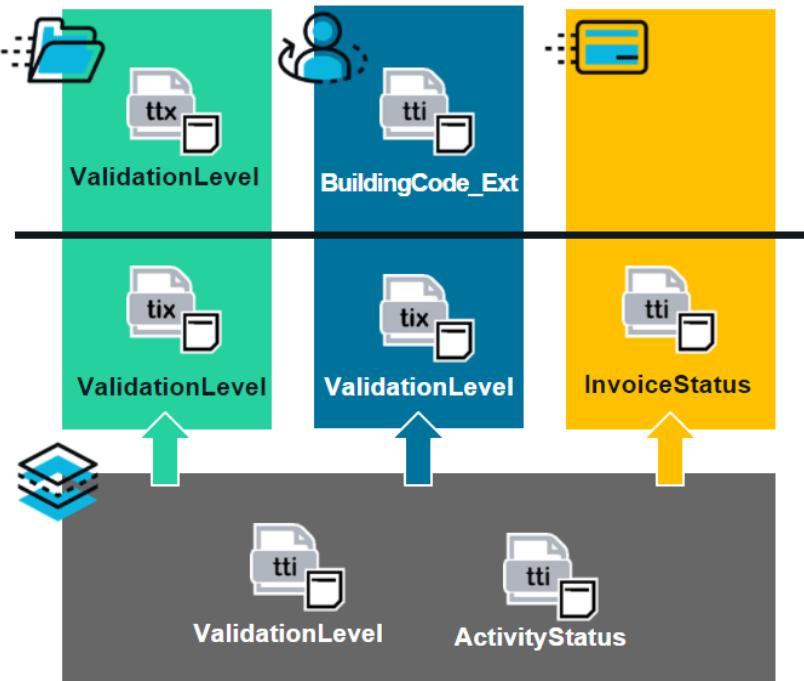

- A Typekey field is an entity field associated with a specific Typelist
- Referenced Typelist contains the list of possible values for the Typekey field
 - The Typekey field can point to one of these Typecodes

For an entity to be able to access and use a typelist, you need to define a <typekey> element on that entity. Use the <typekey> element to specify the typelist in the entity metadata.

Typelists in the data model

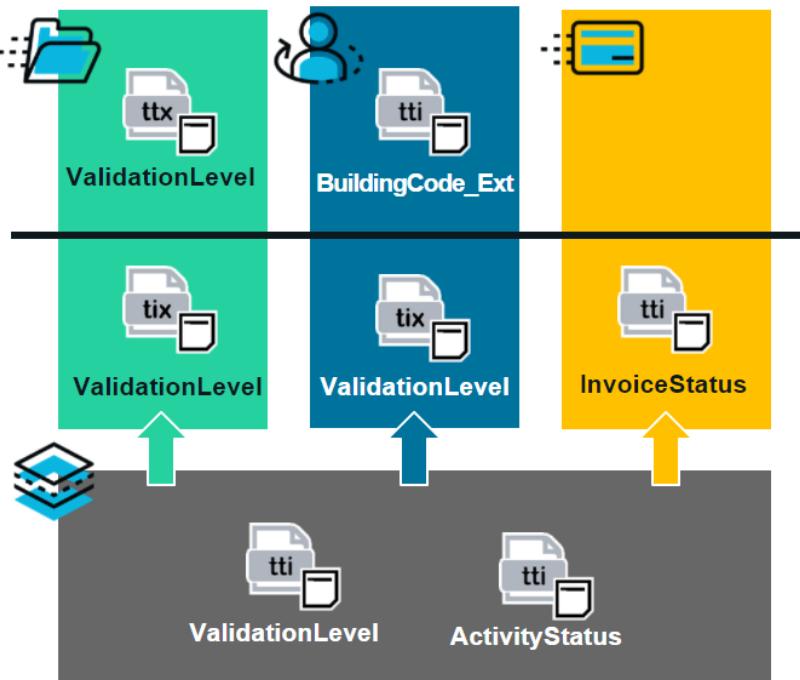

- Follow similar principles as entities
 - Defined as XML files
 - TTI, TIX and TTX files
 - ...\\Metadata\\Typelist folder read-only and contains platform and base application Typelists
 - ...\\Extensions\\Typelist folder contains everything customer specific

TypeLists in the data model (Continued)

For an entity to be able to access and use a typeList, you need to define a <typekey> element on that entity. Use the <typekey> element to specify the typeList in the entity metadata.

TypeLists in the data model (Continued)

- Kinds of TypeLists:
 - ValidationLevel is extendable
 - ActivityStatus is internal
 - BuildingCode_Ext is custom
- Virtual typeLists don't physically exist in the data model

Typelists and Typekey fields in the database

Making changes to Typelists, Typecodes, and Typekeys generate changes to the Data Model. Guidewire recommends that you regenerate the InsuranceSuite application's Data Dictionary if you make any updates to the Data Model. If you have made any mistakes in the previous steps, regenerating the data dictionary helps to identify those mistakes.

Typelists and Typekey fields in the database

- Typelists are stored as database tables
- Typecodes are stored as rows in the table
- Typekeys are stored as foreign key columns in the entity table

ID	TYPECODE	NAME	RETIRE
10001	checking	Checking	FALSE
10002	savings	Savings	FALSE
10003	other	Other	FALSE

BANKNAME	ROUTINGNUMBER	ACCOUNTNUMBER	ACCOUNTTYPE
ACME Credit Union	123-987	345678900	10001
National Bank	745-222	232323566	10001
ACME Credit Union	123-999	112233445	10001
ACME Credit Union	225-999	554433221	10002

Typefilters

A Typefilter defines a named subset of the Typecodes that could be used as value for the associated Typekey field that references this Typelist.

Typefilters

- A Typelist filter causes the Typelist to display only a subset of the Typecodes for that Typelist
- Multiple Typefilters can be defined in a Typelist
- A Typekey field can reference at most one Typefilter from the associated Typelist

Element	Code	Name	Priority
typelist	YesNo	Yes, No, or Un...	
	typecode yes	Yes	10
	typecode no	No	20
	typecode unknown	Unknown	30
typefilter	YesNoOnly	Only display Y...	
	includ yes		
	includ no

What are some of the differences between the files in the ... \\Metadata\\Typelist\\ and ... \\Extensions\\Typelist\\ folders?
(Answer)

Answer

What are some of the differences between the files in the ... \\Metadata\\Typelist\\ and ... \\Extensions\\Typelist\\ folders?

- Files under Metadata are read-only and are specific to the base configuration.
- You cannot create Typelist files in the Metadata directory but can create Typelist files in the Extensions directory.
- Only internal Typelist extension files (TIX) are in the Metadata directory.
- Only external Typelist files (TTX) are in the Extensions directory.
- Both directories contain Typelist (TTI) files.

Answer

-- What does a Typefilter do?

Defines a named subset of the Typecodes that could be used as value for the associated Typekey field that references this Typelist.

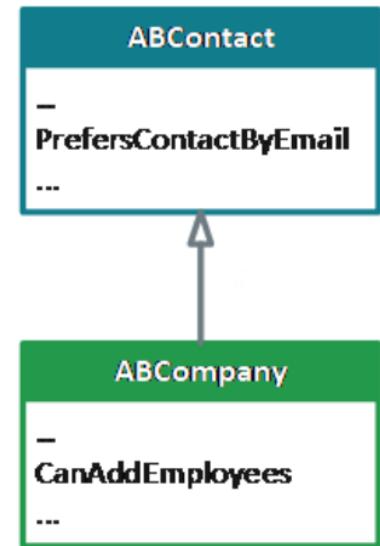

Subtype entity

Note: Language primitives also have types. For example, the code "typeof 29" is valid Gosu, and it returns java.lang.Integer, which is a Type. In other words, Integer is a subtype of Type.

Subtype entity

- A subtype is an entity that is a child to a supertype entity and inherits all fields and methods from the supertype
- Example:
 - ABContact is the supertype
 - ABCompany is the subtype
 - ABCompany inherits PrefersContactByEmail from ABContact
 - ABContact does **NOT** inherit CanAddEmployees

Notes

Example: subtype hierarchy in TrainingApp

There is one subtype entity excluded for the diagram because it is not directly relevant to the configuration lab work: ABUserContact. ABUserContact represents a TrainingApp user and defines a user's contact details.

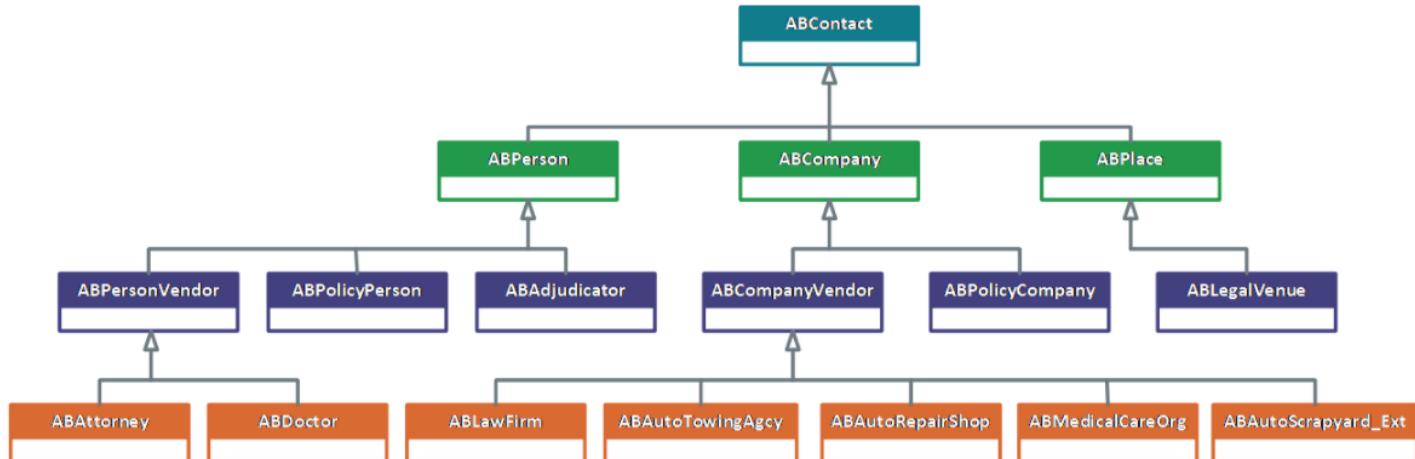

ABContacts are organized into a set of subtypes. The organization of the hierarchy helps to model information about contacts. Information common to all contacts can be established at the ABContact level. It is automatically inherited by all of its subtypes. Information specific to an ABPerson can be defined at the ABPerson level. It is inherited by all of its subtypes, but information on the ABPerson subtype is not available to ABCompany or ABPlace.

In the ABContact hierarchy, an ABPolicyPerson is a person who owns a policy issued by the carrier (such as an individual with a personal auto policy). An ABPolicyCompany is a company which owns a policy issued by the carrier (such as a construction company with a workers' compensation policy).

Subtyping is also used within the three primary applications. For example:

- BillingCenter's Activity, Plan, and Contact entities

Example: subtype hierarchy in TrainingApp

Additional subtype hierarchy examples

In ClaimCenter:

- A transaction is used to denote the movement of money either into a reserve line or from a reserve line to a payment.
- An incident describes a damaged or lost property or coverable.

In PolicyCenter:

- A job is used to manage a policy transaction, which either creates or modifies a policy.
- A plan detail is used to manage plans, which typically identify how the insured will be billed for or will pay for the policy. This information is passed to the billing system.

In BillingCenter:

- A plan is used to store information about how Invoicing, Commissions, Billing and Delinquency are performed.
- A charge pattern is used to define billing behaviors for each kind of charge, such as installment invoicing for Premium charges versus one time billing for Taxes.

Additional subtype hierarchy examples

All applications

Contact: Person, Company, Place, ...

ClaimCenter

Incident: InjuryIncident, TripIncident, PropertyIncident

Transaction: Payment, Recovery, Reserve, ...

PolicyCenter

Job: Submission, Renewal, Cancellation, Reinstatement, ...

PlanDetail: BillingPlanDetail, PaymentPlanDetail, ...

BillingCenter

Plan: BillingPlan, CommissionPlan, DelinquencyPlan, ...

ChargePattern: ImmediateCharge, ProRataCharge, ...

Subtypes in the database

ABContact is the supertype for the three primary subtypes : ABPerson, ABCCompany, and ABPlace. There are a total of 17 subtypes of ABContact for TrainingApp.

For columns not relevant to a given row's subtype, the column contains a null value. For example, Lily Watson is an ABAttorney and therefore the Name column is null value. Similarly, Express Auto, an ABAutoRepairShop, shows null values for FirstName and LastName. TaxID is a field defined in the ABContact entity. Both Express Auto and Lily Watson have TaxID encrypted values.

High degrees of subtyping of a single supertype can result in a highly denormalized database table with many columns and large row sizes. For purists seeking high degrees of normalization in database tables, subtyping will appear abhorrent.

In Guidewire applications, subtypes represent a trade-off between data model configuration flexibility and database performance. High degrees of normalization require numerous joins when querying. In many ways, it can be easier to add columns to a table rather than create more table objects in a database that require numerous joins for queries.

Subtypes in the database

- Typelist and entity table define supertype and subtype relationships
- Supertype entity table contains subtype columns in denormalized form
 - **ID, TaxID and Name** from ABContact
 - **FirstName and LastName** from ABPerson
 - **AttorneyLicense** from ABAttorney
 - **IsFranchise** is from ABAutoRepairShop
- Irrelevant columns for subtype are null

ID	TYPECODE
1	ABAdjudicator
2	ABAAttorney
3	ABAAutoRepairShop
4	ABAAutoScrapYard_Ext
5	ABAAutoTowingAgcy
6	ABCompany
7	ABContact
8	ABDoctor
9	ABLawFirm
10	ABLegalVenue
11	ABMedicalCareOrg
12	ABPerson
13	ABPlace
14	ABPolicyCompany
15	ABPolicyPerson
16	ABUserContact
17	ABCompanyVendor
18	ABPersonVendor

Review: subtypes

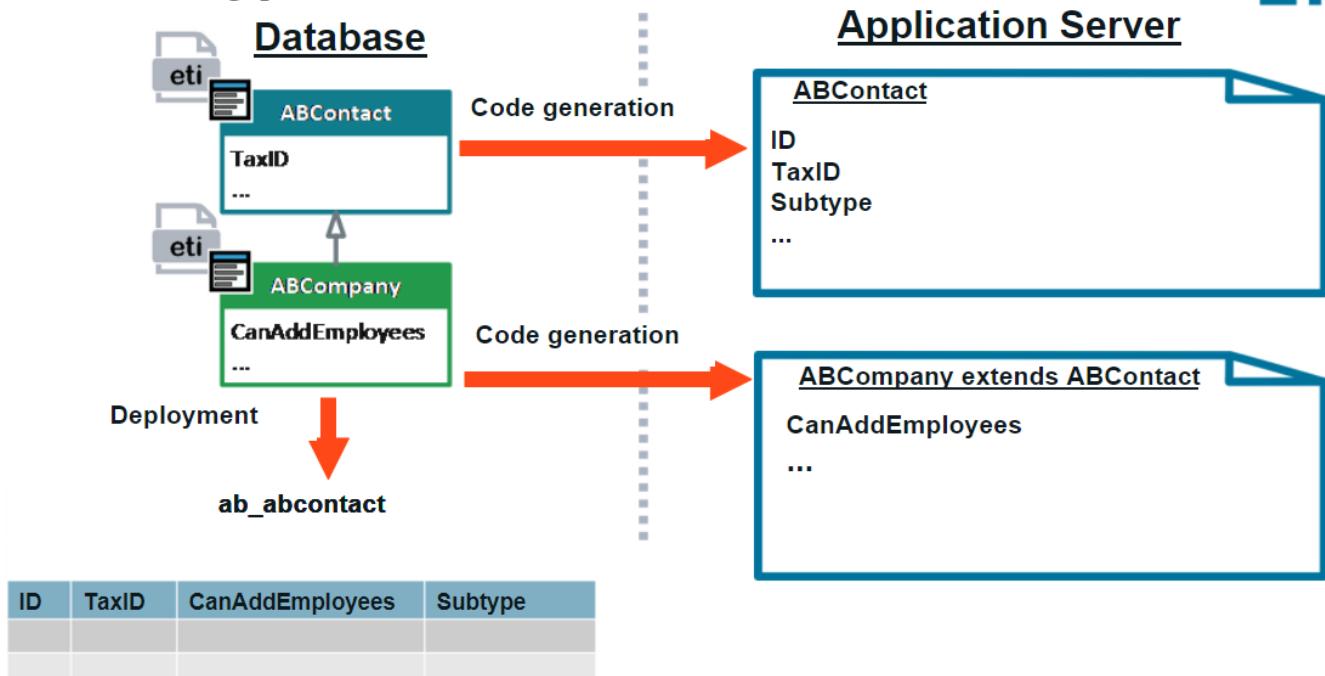

In object-oriented design, a class can be extended by a child class or subclass. Every field and method declared at the parent class is added to the child class automatically. In object-oriented design, subclass extensions from a superclass is called inheritance.

Guidewire subtypes also make use of inheritance. Every subtype has its own generated Java class. This class inherits all fields and methods of the parent class.

In most cases, a database table corresponds to one data model entity, and therefore one database-backed Gosu class. One exception to this is where subtypes are concerned. If an entity is subtyped, then the database table corresponds to the top-level data model entity and all of its subtype entities. The table then also corresponds to one top-level database-backed Java class and all of its subclasses.

For example, the `ab_abcontact` table has column for `CanAddEmployees`. This field only applies to ABContacts that are of type ABCompany. For ABPersons, that column will have null value.

Review: subtypes

Answer

What is a subtype entity?

A subtype is an entity that is a child to a parent entity and inherits all fields from the parent.

What is a subtype entity extension?
(Answer)

Answer

-- What is a subtype entity extension?

A subtype extension is an entity extension of a base application subtype entity.

◀ PREV NEXT ▶

Guidewire application UI framework

A PCF is an XSD-validated XML document containing elements that describe the structure, layout, and behavior of the web user interface. The majority of this content is defined at the application level, though some is defined at the platform level.

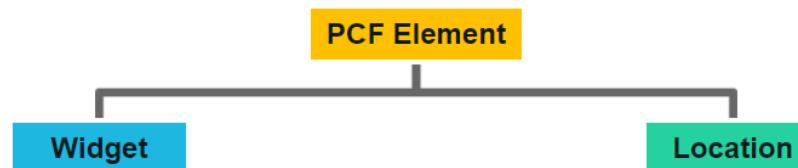

A widget is a PCF element that will be converted into HTML and displayed. This does not mean that a widget itself will always be visible. Some of the widgets are containers that are only used to group other widgets in a specific layout format. Widgets can specify permissions that the logged in user needs to view/edit the data.

A location is a PCF element that a user (or the application itself) can navigate to. It is used to define how users move from one area of the user interface to the next. A location usually specifies:

- 1) which part of the browser window will be updated if the application/user navigates to the location
- 2) what are the permissions that the logged in user needs to view/edit the data in that location

Note: Both Widget and Location are conceptual representations in this diagram. There are no <Widget /> or <Location /> elements.

Guidewire application UI framework

Displayable elements of the user interface rendered into HTML

Navigable places in the application that a user or the application itself can navigate to

- The PCF (Page Configuration Format) object model is a proprietary application framework used to create all Guidewire end-user interfaces
- By using the Studio Page Configuration (PCF) editor, you can modify an existing PCF file or add a new PCF file and graphically build and manage its elements

Guidewire Proprietary & Confidential – DO NOT DISTRIBUTE

Page 4

Atomic widgets

Atomic widgets are individual field items such as inputs, cells, or buttons. They will always be defined within a container widget or location.

Note: Both Widget and Location are conceptual representations in this diagram. There are no <Widget /> or <Location /> elements. Atomic Widget is also a conceptual representation. There is no <Atomic Widget /> element.

Atomic widgets

- An atomic widget is the smallest building block of the user interface
 - displays individual data value
 - executes individual action

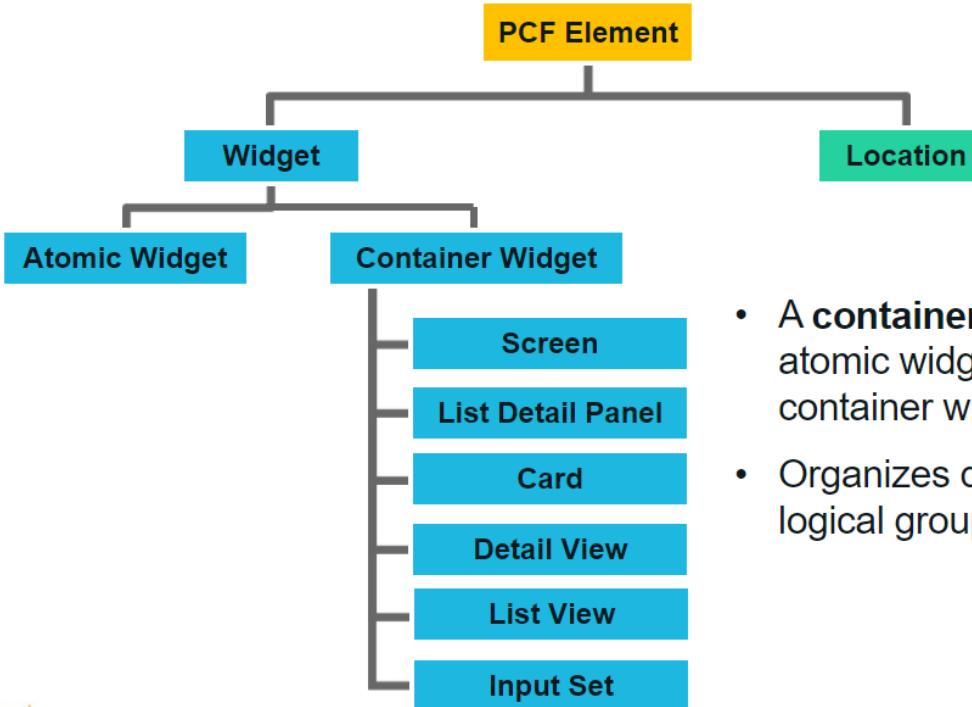

Container widgets

Container widgets hold other widgets. Each one can be defined either in its own file or as a child container within some other PCF element file.

Note: Both Widget and Location are conceptual representations in this diagram. There are no <Widget /> or <Location /> elements. Similarly, both Atomic Widget and Container Widget are conceptual representations. There are no <Atomic Widget /> or <Container Widget /> elements.

The PCF object model is container-based. Each UI element is modeled as an object, which may contain other objects. The hierarchical structure simplifies the task of locating and modifying visual elements. Furthermore, each element can be declared as an independent and therefore reusable element.

Container widgets

- A **container widget** is a collection of atomic widgets and/or other container widgets
- Organizes data and functionality into logical groups

Page 7

Detail View Panels

Detail view panels are generally designed to use widgets to organize and manage a collection of related pieces of information that constitute a single record. The most obvious example is the set of individual fields of an instance of an entity such as User, Claim, or Policy. There are no constraints imposed by the system as to what information can be displayed by a detail view; however, the view could present information from multiple entities that do not even have to be related to one another, in addition to information that does not derive from an entity at all (such as calculated or static values).

The purpose of a detail view panel, however, and the recommended practice behind their use, is to present the user with all of the detailed information that is relevant to that interface, and no information that is irrelevant. In general, this means displaying information about the fields of a particular entity and possibly fields from a small number of closely related entities.

Detail view panels must contain at least one column and can contain as many columns as necessary to present the widgets in the most effective way for the user.

List View Panels

Just as a detail view panel is designed to allow the user to view detailed information about a single record, a list view panel is designed to allow the user to view summary information about a collection of records.

List View Panels

Bank Name	Routing Number	Account Number
ACME Credit Union	123-987	345678900
National Bank	745-222	232323566

Add Remove

Bank Name *	Routing Number *	Account Number *	Account Type *
ACME Credit Union	123-987	345678900	Checking
National Bank	745-222	232323566	Checking

- Table organizes information that allows the user to view information about multiple records at the same time
- Uses a small number of atomic widgets to display the most relevant information
- Screens and secondary views can reference
- Often referred to as "List View"

For more information on Detail View Panels, see the product documentation.

Input Sets

The screenshot shows a user interface for managing personal information. At the top, there are three tabs: 'Person Info' (which is active), 'Phone & Addresses', and 'Bank Accounts'. Below the tabs is a toolbar with a pencil icon. The main area is divided into sections: 'Name' and 'Tax Info'. The 'Name' section contains fields for Full Name (William Andy), Prefix (<none>), First Name (William), Middle Name (empty), Last Name (Andy), and Suffix (<none>). The 'Tax Info' section contains fields for Tax ID (*****), Tax Filing Status (<none>), Date of Birth (MM/dd/yyyy), Gender (<none>), and Marital Status (<none>). A red box highlights the 'Tax Info' group of fields. A blue button labeled 'Input Set' is located at the bottom right of this highlighted area.

- Set of atomic widgets grouped together
 - Could be reused together
 - Common visibility / editability condition could be applied across multiple widgets
 - The input set could be targeted with a partial page update to improve UI performance
- Input Sets fit some attributes of the primary containers
 - They can contain atomic widgets and organize them into logical groups
- BUT:
 - Input Sets must be embedded into Detail View Panels
 - Cannot be referenced by secondary views
 - Cannot have a toolbar directly associated with them

Page 11

Secondary containers

A secondary container organizes primary containers.

Secondary containers

- A **Card** is a collection of cards, with each card containing Detail Views or List Views
- A **List Detail Panel** contains a top List View and a bottom view panel that display data about the selected list item

The screenshot shows a user interface for managing a person's details. At the top, a header bar displays "Person: William Andy". Below it, a "Details" section contains tabs for "Person Info", "Phone & Addresses", and "Bank Accounts", with "Person Info" currently selected. Under "Person Info", fields for Name, Full Name, Prefix, First Name, Middle Name, and Last Name are displayed. To the right, a "List Detail Panel" is shown, which includes a "Addresses" section and an "Address Detail" section. The "Addresses" section lists three address entries: "Home" (345 Fir Lane, La Canada, CA 91352), "Business" (1 Main Street, Santa Monica, CA 90401), and "Billing" (1 Old Harbor Lane, Marina Del Rey, CA 90292). The "Address Detail" section provides detailed information for the selected "Home" address, including Address Type (Home), Description (Home), Country (United States), and Address 1 (345 Fir Lane).

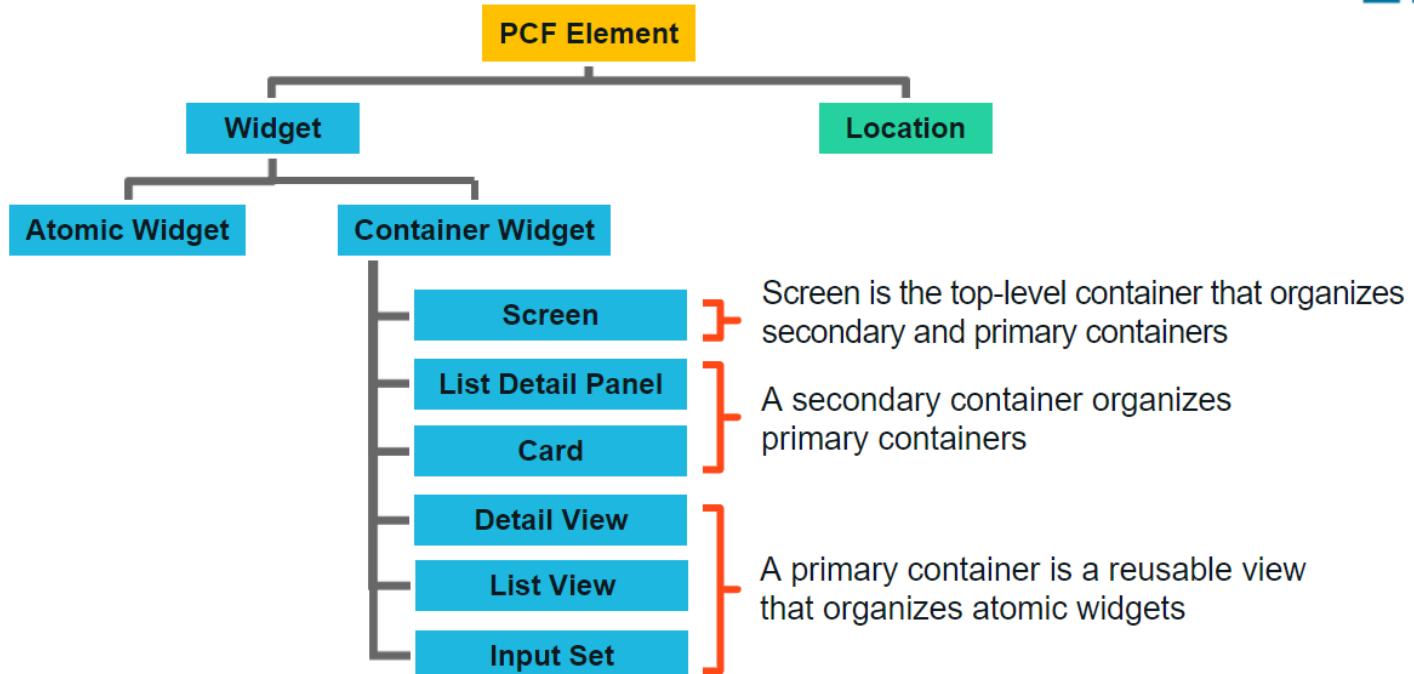

Top-level container widget

Top level containers organize secondary and primary containers.

Top-level container widget

Shown here is an example of a Screen.

Screen

Every atomic widget, primary view, and secondary view is contained (directly or indirectly) in a screen.

Review: Container widget hierarchy

The arrow indicates that A can contain B. For example, a List View Panel can contain Atomic Widgets but cannot contain a Detail View Panel.

Container widgets can be classified in four categories:

1. The lowest level is comprised of atomic widgets.
2. Atomic widgets can be directly contained only by primary views (detail view panels and list view panels). The purpose of a primary view is to organize atomic widgets into logical groups.
3. Secondary views (card view panels and list detail panels) organize primary views. Secondary views cannot directly contain most atomic widgets.
4. Screens are the top-level containers. Screens are used to connect what is displayed in the user interface with how users navigate through the user interface. A screen can directly contain both primary views and secondary views, but it cannot directly contain most atomic widgets.
5. There is one exceptional case, when a primary view can be placed into another primary view. This will be discussed

Review: Container widget hierarchy

- Screen
 - Top-level container that organizes secondary and primary containers
 - Referenced by locations: Page, Wizard, Popup, Worksheet
- Secondary containers
 - Collections of primary containers organized for usability
 - Could also contain other secondary containers
- Primary containers
 - A reusable view that organizes atomic widgets
 - In certain cases, a Detail View could also contain a List View Panel
- Atomic widgets
 - Individual elements of data and/or functionality

Define the broad purpose for each element category:

Answer

Define the broad purpose for each element category:

- A) Atomic widgets
- B) Container widgets
- C) Locations

The correct responses are:

- A) Atomic widgets display individual elements of data and/or functionality.
- B) Container widgets group atomic widgets into logical groups.
- C) Locations define how users move from one place in the application to the next.

What does a PCF file define?

Answer

What does a PCF file define?

A PCF file defines a container widget or location and its contents.

- Detail View must have at least one Input Column
- Input Columns organize layout and input widgets

Inline widget vs. PCF file

When a container such as a detail view panel is a top-level container, it is reusable. A top-level container is a PCF file. If the container is likely to be needed in multiple places, create a PCF file for the container. A Detail View Panel is PCF file that is ideal for multiple references. Other PCF files can reference the reusable container using a reference widget. In TrainingApp, the ABContactSummaryPage contains a Screen with a Panel Ref that references ABContactSummaryDV. Panel Ref widgets are discussed later in this lesson.

When a container such as detail view panel is declared as an inline child container, it is not reusable. Other containers cannot reference an inline container. A Detail View widget is defined in a Screen, Card, or a List Detail Panel. It is possible to define a variable for a Detail View widget object, but this is uncommon. A Detail View widget inherits the root object associated with its parent.

Inline widget vs. PCF file

Detail View widget

- Differences:
 - Not reusable
 - Inherits parent root object
 - Created as a Detail View widget in the parent container's PCF file
- Similarities:
 - It can exercise control over all elements

Detail View PCF file

- Differences:
 - Reusable
 - Takes a root object
 - Created as separate PCF file and filename ends with DV
- Similarities:
 - It can exercise control over all elements

If the container is likely to be needed in multiple places, create a reusable PCF file

Page 3

[PREV](#) [NEXT](#)

Atomic widgets

A widget is a PCF element that a Guidewire application renders into an HTML object. Buttons, menus, text boxes, and dropdown lists are all examples of PCF elements that are considered widgets. Some widgets that are not visually presented in the web browser, but are rendered as an HTML object, such as a hidden input.

Display key is a Guidewire application mechanism that allows locale-specific texts to be dynamically rendered in the browser depending on the user's internationalization language settings. Every key has one or more localized text values. When a PCF file references a display key, the application converts the key to one of the localized values depending on the user's language settings.

Atomic widgets

- An **atomic widget** is a graphical user interface element that is non-divisible
- An atomic widget displays individual data values and/or executes individual actions
- Input and cell widgets bind data values
 - Data values often associated with root objects, query objects, or related objects

The screenshot shows a 'Addresses' form with a list of addresses and a detailed view for the first address. The first address is highlighted with a red box. The 'Update' button at the top right of the list is also highlighted with a red box. The detailed view panel below shows fields for Address Type (Home), Description (Home), Country (United States), Address 1 (345 Fir Lane), City (La Canada), County (Los Angeles), State (California), and ZIP Code (91352-####). The 'City' field is also highlighted with a red box.

Display keys and widgets

Display keys and widgets

- Widgets often include a label rendered with them in the UI
 - It's a recommended practice to use Display Keys to display static text in the UI
 - Display Keys support easy text reusability

[◀ PREV](#) [NEXT ▶](#)

What is a display key?

Answer

What is a display key?

A display key is an abstract display value referenced by a widget's label property. It can have one or more language-specific values, and when the UI is rendered, the value matching the user's language is used.

If you create a widget and specify only the ID, name, and label, is the widget visible? Editable? Required?

Answer

-- If you create a widget and specify only the ID, name, and label, is the widget visible? Editable? Required?

The widget will be visible, not editable, and not required.

Iterator buttons and row iterators

- Properties of Row Iterator govern functionality of Iterator buttons (Add|Remove)
 - toAdd - action to take when Add is clicked
 - toRemove - action to take when Remove is clicked

The screenshot illustrates the configuration of a Row Iterator and its corresponding user interface. On the left, the 'Properties' panel shows the 'Row Iterator' properties. The 'Basic properties' section includes 'editable*', 'elementName*', 'id', 'toAdd', 'toCreateAndAdd', and 'toRemove'. The 'toAdd' and 'toRemove' fields are highlighted with red boxes and connected by a red arrow to the 'Add' and 'Remove' buttons respectively in the 'Bank Accounts' tab of the main interface. The main interface displays a 'Person: William Andy' record with tabs for 'Person Info', 'Phone & Addresses', and 'Bank Accounts'. The 'Bank Accounts' tab contains a table with columns for Bank Name, Routing Number, and Account Number. Buttons for 'Add' and 'Remove' are located above the table, with 'Add' being green and 'Remove' being grey.

Iterator buttons and row iterators

The add button is usually configured one of the following two ways:

- When the user clicks Add, a new empty row (object) is inserted in the List View. The user can initialize the row (object) by simply editing the cells.
- When the user clicks Add, a popup opens. The popup creates an empty object and displays all the fields of the object. The user can initialize the object by specifying the different fields in the popup. When the user clicks OK, the initialized object will be inserted to the List View and displayed as a row.

The first one is typically used when the List View displays all the fields that need to be initialized. The second approach is used when the List View displays only a few important fields of the object, but the object has more fields that need to be initialized during creation. In the example, the List View displays 3 fields of the Vendor Evaluation, but the object has other fields that may need to be initialized, so going with the second approach seems to be the better solution in this case.

Note: To implement this second use case, you would also need to configure a creational popup. Creating objects with popups is out of scope for this course.

Iterator buttons and row iterators

Typical configuration

- The typical method for the Add button is shown here, which is used when the List View displays all the fields that need to be initialized
- The user clicks the Update button, which puts the screen in edit mode
- The user clicks the Add button, and a new empty row is inserted in the List View. The user can initialize the row by simply editing the cells.

Notes

Editable hierarchy

The following summarizes the default value of the editable property for each element:

A **list view** panel's editable property is blank. The property is not required. (A list view panel with no specified editable property is editable.)

A **row iterator**'s editable property is blank, but this property is required. To have editable cells, it must be set to true, or to a condition that evaluates to true.

A **row**'s editable property is blank. The property is not required. (A row with no specified editable property is editable.)

A **cell**'s editable property is false. To have the cell be editable, you must set the property to true, or to a condition that evaluates to true.

In practice, the two elements you must explicitly set to editable to get editable cells are the **row iterator** and the **cells** that are to be made editable.

Editable hierarchy

[◀ PREV](#) [NEXT ▶](#)

List View Panels

Just as a detail view panel is designed to allow the user to view detailed information about a single object, a list view panel is designed to allow the user to view summary information about a collection of objects.

List View Panels

Verification Check					
Bank Name	Routing Number	Account Number	Account Type	Verified?	Created On

<input type="checkbox"/> ACME Credit Union	225-999	554433221	Savings	Pending	06/19/2018

- A List View Panel is a container widget that allows the user to view information about multiple objects at the same time
- Often referred to as "List View"
- In certain cases, users can also edit the data displayed in the List View

Typical List View Panel structure

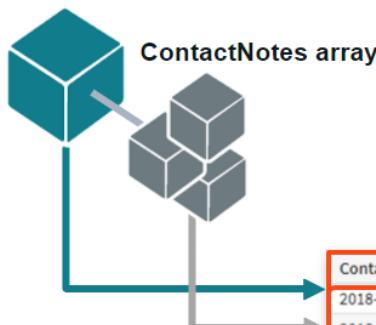

Row widgets organize the layout of the cells for an object instance when the row iterator is manipulating that instance. Row widgets do not perform any "navigation" within the collection of object instances. Adding a second row widget would not display two different objects when the page is rendered but would arrange the cells for each instance across two rows. The generated markup for a row widget is a <TR> HTML tag.

The List View's root object typically the parent of the array and not the array itself. This is because the parent entity automatically provides the addTo<ArrayName> and removeFrom<ArrayName> functions that we can use to make the List View later editable. In other cases, the root object could be the set of elements that needs to be displayed. For example, the List View displays the results of a database query. In this case there is not parent object, thus there are not addTo and removeFrom functions.

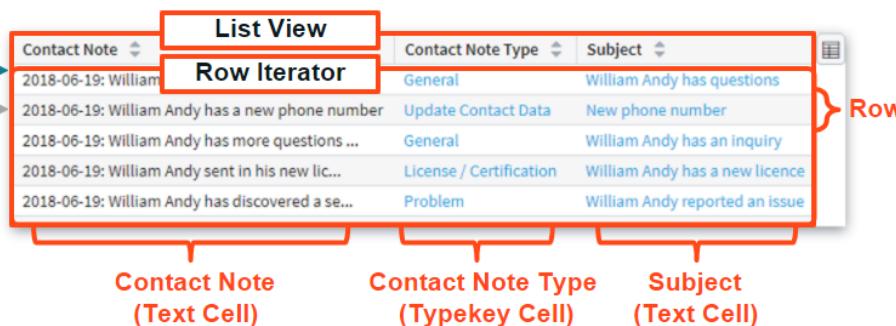

Typical List View Panel structure

ABContact as root object

- List View Panel typically takes single root object that has an array of entities to process
- Row Iterator processes the related array and produces a row for each entity instance
- Row contains one or more Cell widgets
- Cell displays an individual field of an entity

Page 5

Row Iterator

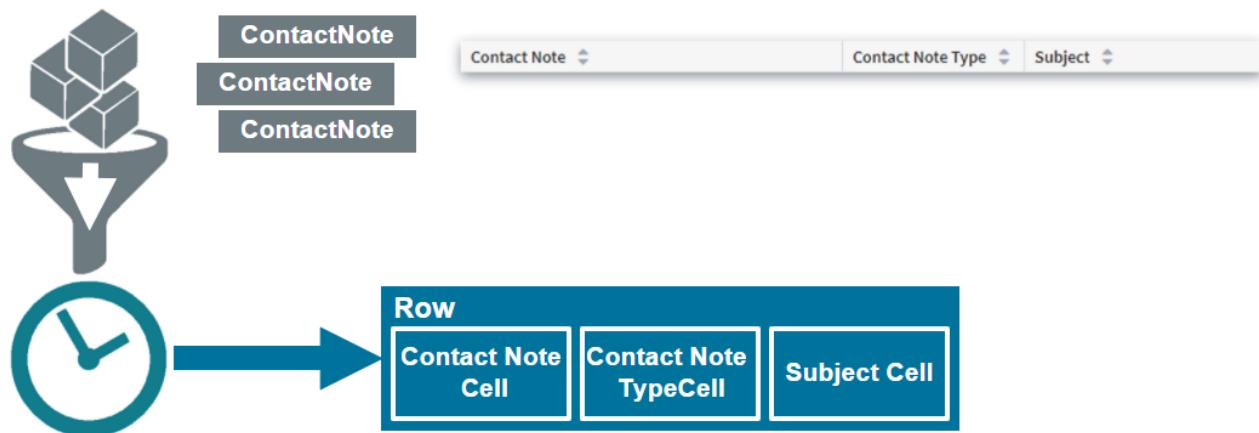

The PCF architecture has several different types of iterators, including:

- Menu item iterators, which take a set of objects and generate one menu item for each.
- Panel Iterators, which take a set of objects and generate one panel (typically, one detail view) for each.
- PolicyCenter Coverage Iterators, which take a set of coverages associated with a covered item (such as a vehicle) and generate one coverage input for each coverage.

Row Iterator

- An **Iterator** is a widget that takes a set of items and performs the same set of actions for each member
- A **Row Iterator** takes a set of objects (array or query results) and renders each object as one row of cells

Guidewire Proprietary & Confidential – DO NOT DISTRIBUTE
© 2021 Guidewire Software, Inc. For information about Guidewire's trademarks, visit <http://guidewire.com/legal-notices>.

Page 6

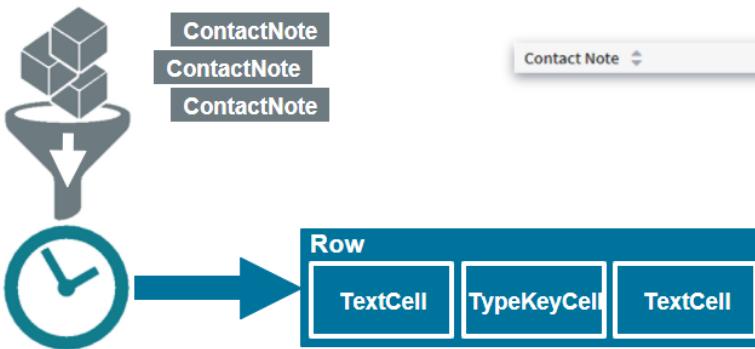

Row iterator: no objects processed

The Row Iterator always knows which object is associated with the current row. You can simply use the variable defined in the **elementName** property whenever you have to reference the object in the current row (e.g. configuring a cell's value/action property).

Row iterator: no objects processed

- Row Iterator has 4 required properties:
 - **value**: anABContact.HistoryEntries – the set of elements to process
 - **valueType**: HistoryEntry[] – the type of the set of elements
 - **elementName**: currentHistoryEntry – points to the object in the array associated with the row
 - **editable**: false – whether the cells can be edited or not

Guidewire Proprietary & Confidential – DO NOT DISTRIBUTE

Inline widget vs. PCF file

To enable a container widget such as List View to be reusable, it needs to be defined as a top-level container in a PCF file. This means that a top-level container itself is a PCF file. If the container is likely to be needed in multiple places, create a PCF file for the container. A List View Panel is PCF file that is ideal for multiple references. Other PCF files can reference the reusable container using a reference widget. In TrainingApp, the ABContactHistoryPage contains a Screen with a Panel Ref that references ABContactHistoryLV. PanelRef widgets are discussed later in this lesson.

When a container such as List View panel is declared as an inline child container, it is not reusable. Other containers cannot reference an inline container. A List View Panel widget is defined in a Screen, Card View Panel, or a List Detail Panel. It is possible to define a variable for an ListViewPanel widget object, but this is uncommon. A List View panel widget inherits the root object associated with its parent.

Inline widget vs. PCF file

List View PCF File

- Differences:
 - Reusable
 - Takes a root object
 - Created as separate PCF file and filename ends with LV
- Similarities:
 - It can exercise control over all elements

List View Widget

- Differences:
 - Not reusable
 - Inherits parent root object
 - Created as a List View widget in the parent container's PCF file
- Similarities:
 - It can exercise control over all elements

If the container is likely to be needed in multiple places, create a reusable PCF file

Answer

In a List View:

- A) What type of widget displays individual fields of data?
 - B) What type of widget organizes the individual fields of data?
-
- A) *Cell widgets*
 - B) *Row widgets*

A list view typically needs a toolbar, even if it is read-only. Why?
(Answer)

Answer

-- A list view typically needs a toolbar, even if it is read-only. Why?

The toolbar is needed for the paging controls. These controls are used to view each page of rows if the number of rows is greater than what can be displayed at one time.

In what way is embedding a List View Panel in a detail view panel different from embedding a list view panel in a screen? (Answer)

Answer

-- In what way is embedding a List View Panel in a detail view panel different from embedding a list view panel in a screen?

To embed a list view panel in a detail view panel , use a List View Input widget. To embed a list view panel in a screen (or card view panel or List Detail Panel , you use a Panel Ref widget.

Page 4

[◀ PREV](#) [NEXT ▶](#)

Note: It is important that Input Sets are not referenced by secondary views, don't have a toolbar directly associated with them, and are embedded into a Detail View Panel.

Review: Input Sets

The screenshot shows a 'Basic Information' form with various fields. A specific section, 'Primary Address', is highlighted with a red border. This section contains fields for Country (United States), Address 1 (345 Fir Lane), Address 2, Address 3, City (La Canada), County, State (California), ZIP Code (91352-####), Address Type (Home), Description, and Valid Until. Below this section is a blue button labeled 'Input Set'.

- Set of atomic widgets grouped together
 - Could be reused together
 - Common visibility / editability condition could be applied across multiple widgets
 - The input set could be targeted with a partial page update to improve UI performance
- Input Sets fit some attributes of the primary containers
 - They can contain atomic widgets and organize them into logical groups
- BUT:
 - Input Sets must be embedded into Detail View Panels
 - Cannot be referenced by secondary views
 - Cannot have a toolbar directly associated with them

Widgets that need to vary

A common scenario in implementations is changing the appearance of a widget in the UI based on business requirements.

Widgets that need to vary

- In some cases, widgets need to vary significantly based on business scenario
- How could the requirement be implemented?

Page 4

Addressing all scenarios within one PCF

For user interfaces that need different structures, you could include all the possible structures in a single PCF file. Including all the possible variants in a single PCF file adds to the complexity of the PCF and eliminates the possibility of reusable containers. In addition, much of the conditional logic becomes overly repetitive. Developers of applications prefer working with smaller components; they are easy to create, debug, modify, and maintain.

Addressing all scenarios within one PCF

if contact is adjudicator

if contact is attorney

if contact is doctor

Addressing scenarios with multiple PCFs

When a single PCF cannot easily accommodate a variety of business cases, it is often easier to create a set of PCFs, one for each use case. Each version needs a value to identify the use case it is designed for. When the PCF is called, it is called by both its name and its "use case". Modes exist in the PCF architecture to implement this "use case" versioning.

Page 6

◀ PREV ▶ NEXT

There is no requirement for modal PCFs to come in sets. It is possible to create a single PCF with a mode that had no counterparts. This sort of PCF would behave in exactly the same way as a PCF that didn't use modes, which would mean there was no benefit to having made the PCF modal. Therefore, in practice, modal PCFs always come in sets of PCFs.

A modal PCF can have multiple modes. In the slide example, the first SubtypeInfoInputSet is used for contacts of subtype ABPerson or ABPolicyPerson.

Modes

- **Mode** is a property used for PCFs appropriate for a given business scenario
 - Mode identifies which scenario(s) the PCF is for
 - Modal PCFs always come in sets
- Every PCF must have:
 - Same ID
 - Same number, type, and order of required variables
 - One or more unique modes (runtime error occurs if referenced mode belongs to multiple PCFs in same set)

SubtypeInfoInputSet

mode = ABPerson, ABPolicyPerson

License Info

Driver's License	2WED458
State	Washington

SubtypeInfoInputSet

mode = ABAdjudicator

License Info

SubtypeInfoInputSet

mode = ABAttorney

License Info

Law License	JX3-AK7-309921
Specialty	Workers' Compensation

SubtypeInfoInputSet

mode = ABDocor

Medical Specialty

Category	General Care
Specialty	Internal Medicine

Default mode

In the slide example, the default PCF is blank. If a SubtypeInfoInputSet is referenced but the mode it references cannot be found (such as, for example, a reference to SubtypeInfoInputSet with the mode ABPropertyInspector), then the default PCF is used.

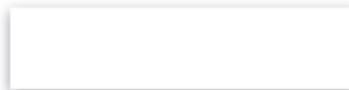

In some situations, the "default" mode is assigned to a PCF that has other non-default modes. For example, since all person contacts are either of type ABPerson or one of its children, it would be possible to have assigned ABPerson, ABPolicyPerson, and default to the first SubtypeInfoInputSet.

Default mode

- Modal PCF sets include one PCF with mode of "default", which is used when something references a mode that doesn't otherwise exist
- "default" must be lower case
- Runtime error occurs if unknown mode is called and no "default" widget exists

SubtypeInfoInputSet mode = default

SubtypeInfoInputSet mode = ABPerson, ABPolicyPerson

License Info	
Driver's License	2WED458
State	Washington

SubtypeInfoInputSet mode = ABAdjudicator

SubtypeInfoInputSet mode = ABAttorney

License Info	
Law License	JX3-AK7-309921
Specialty	Workers' Compensation

SubtypeInfoInputSet mode = ABDoctor

Medical Specialty	
Category	General Care
Specialty	Internal Medicine

Common uses of modal PCFs

In PolicyCenter, modes are also used to accommodate variations in policy transaction type (submission, change, renewal, cancellation, and so on).

Common uses of modal PCFs

- Modes can be used with:
 - Detail view panels
 - Card view panels
 - Input sets
 - List view panels
 - Info bars
 - Screens
 - ...and more (refer to documentation)
- Modes are often used to accommodate variations in:
 - Contact type (individuals, companies, and so on)
 - Line of business (auto, workers' comp, property, and so on)

Page 9

[◀ PREV](#) [NEXT ▶](#)

Modes and subtypes

In the slide example, the first modal PCF is the default mode, and will be used for any contact whose type is not ABAttorney, ABPerson, or ABPolicyPerson.

The second modal PCF has one mode, ABAttorney, and will be used for any contact whose type is ABAttorney.

The third modal PCF has two modes, ABPerson and ABPolicyPerson, and will be used for any ABPerson or ABPolicyPerson contact.

For the diagram shown, the default mode will be used for contacts of type "ABPersonVendor" and "ABDoctor".

In the base application, there is actually an ABPersonVendor subtype in between the ABPerson level and the ABAttorney or ABDoctor level.

Modes and subtypes

- Mode property recognizes explicitly specified subtypes
 - Not aware of a subtype's hierarchy
 - Unspecified subtypes will not render
- In this example, the default mode will be selected for ABPersonVendor and ABDoctor

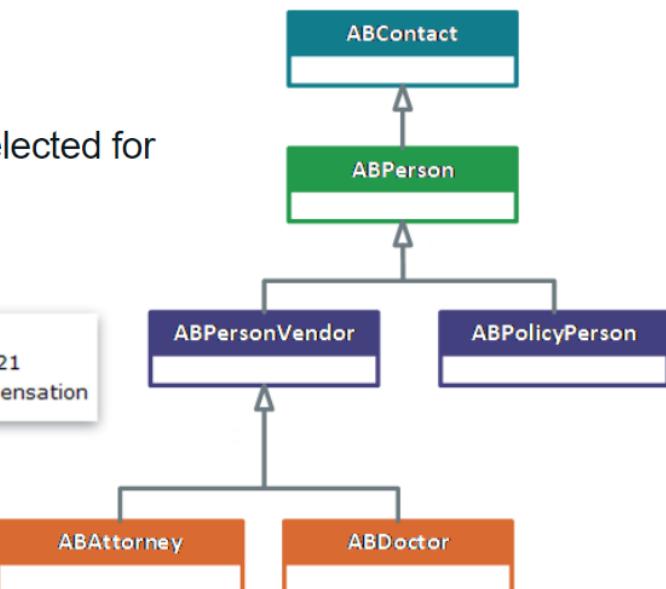

SubtypeInfoInputSet
mode = default

SubtypeInfoInputSet

Page 4

For more information, see the topic, "Introduction to Page Configuration" in the product documentation.

Pages

- A **Page** contains a single screen
 - Pages are used exclusively within Location Groups

The screenshot shows a 'TrainingApp' interface with a sidebar containing 'Actions', 'Summary', 'Details', 'Addresses (3)', 'Notes (5)', 'Social Media', 'Analysis', 'Interactions', and 'History'. The main content area is titled 'Summary' and displays 'Person: William Andy'. It includes tabs for 'Basics', 'Social Media', and 'Analysis', with 'Basics' selected. Below the tabs is a button 'Suggest Least Busy User'. The 'Basic Information' section shows 'Name: William Andy' and 'Public ID: ab:5'. To the right is a 'Flag Entries' panel with a table:

View	Date Flagged	Reason
View	06/19/2018	No email ad

Other sections include 'Assigned User', 'Created On' (06/19/2018), and 'Primary Address' (345 Fir Lane, La Canada, CA 91352).

Location groups

A Location Group can be thought of as a "page group" as it is fundamentally a collection of pages, each with its own screen. Location groups are used to gather together a set of screens that display data about a single primary object (such as a contact, a policy, an account, or a claim) or serve a single major application function (such as searching for data). In the example on the screen, the location group displays data about a claim. Users navigate from one page in a Location Group to the next by clicking the links in the side bar.

All the pages in a Location Group share a common info bar, actions menu, and side bar.

The tab bar appears at the top of the screen and allows the user to navigate to different parts of the application. For example, to view another claim from the Claim dropdown menu, to go to an appropriate search screen or the address book, and so on.

The info bar is the area directly below the tab bar that usually contains icons providing high-level information about the data in the screen area. In the example above, the info bar contains a "car" icon indicating this is a personal auto claim. It shows the name of the insured ("Ins: Ray Newton"), and the date of loss ("Dol: 01/02/2021"). Note that

Wizard example: PolicyCenter

The Wizard in the slide example is the Submission Wizard, which is used to create and modify submissions. A submission ends when it is withdrawn or bound. The outcome of successfully binding a submission is a policy.

Wizard example: PolicyCenter

PolicyCenter wizards are used to create, modify, renew, or cancel policies

The screenshot shows the Guidewire PolicyCenter interface. At the top, there's a navigation bar with links for Desktop, Account, Policy, Contact, Search, Team, and various icons. Below that, a header displays "Submission (Draft)" for "Inland Marine" with effect date "08/29/2018", "Sherman Developments", and account number "D000556767". It also shows the underwriter "Alice Applegate". The main content area is titled "Contractors Equipment". A sidebar on the left lists steps: "Policy Contract", "Policy Info", "Coverage Part Selection", "Buildings and Locations", "Contractors Equipment" (which is selected and highlighted in blue), "Risk Analysis", "Policy Review", and "Quote". Below the title, there are two tabs: "Cov coverages" and "Underwriting Information" (which is active). Under "Underwriting Information", there's a section titled "IM Contractors Equipment Questions" containing several questions with "Yes" and "No" radio button options. The questions are: "Is a guard or watchperson service employed where the equipment is operated or stored?", "Are all employees (including temporaries) trained to handle the equipment they will operate?", "Are equipment operators' MRVs reviewed on a regular basis and maintained?", "At the job and storage sites, is there security lighting?", "Are the job and storage sites fenced in?", "Are there any hazardous or flammable materials stored in close proximity to the equipment?", "Are any of the job and storage sites subject to flooding?", and "Is any of the equipment stored indoors?".

[◀ PREV](#) [NEXT ▶](#)

Popups

Popup screens are designed to mimic the functionality of a true popup (which is an entirely separate window). True popups are difficult to architect because there is no easy way to avoid synchronization errors in which the system tries to update the same object in two separate windows. Popup Locations as architected in Guidewire offer virtually the same functionality while avoiding the synchronization and usability issues.

Popups

- A **Popup** contains a single screen and returns the user to the previous Location once the popup is closed
- Automatically has "Return to <previous location>" link

Return to Summary

The worksheet is an area of the user interface that runs across the bottom. It is visible only when a screen is displayed within it. It is the one area of the user interface that is not always visible.

If multiple worksheets are rendered at one time, the tabs across the top of the worksheets can be used to navigate between worksheets.

Worksheets

- A **Worksheet** contains a single screen rendered in the workspace frame

The screenshot shows the Guidewire TrainingApp interface. At the top, there's a navigation bar with the 'TrainingApp' logo, a search bar, and a contact dropdown. Below the navigation is a sidebar with various tabs: Summary, Details, Addresses (3), Notes (5) (which is selected and highlighted in blue), Social Media, Analysis, Interactions, and History. The main content area is titled 'Notes' and displays a list of contact notes for 'Person: William Andy'. The notes are listed in a table with columns for 'Contact Note' and 'Contact Note Type'. The notes include: '2018-06-19: William Andy has many general qu...', '2018-06-19: William Andy has a new phone number', '2018-06-19: William Andy has more questions ...', '2018-06-19: William Andy sent in his new lic...', and '2018-06-19: William Andy has discovered a se...'. The note type for the first note is 'General'. A large green callout box labeled 'Worksheet' points to the bottom-most note entry field, which is a modal window titled 'Edit Note'. This modal contains fields for 'Edit Note' (with 'Update' and 'Cancel' buttons), 'Contact Note Type' (set to 'General'), 'Confidential?' (radio buttons for 'Yes' and 'No' with 'No' selected), 'Subject' ('William Andy has questions'), and 'Body' ('William Andy has many general questions').

Page 12

Forwards

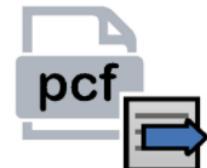

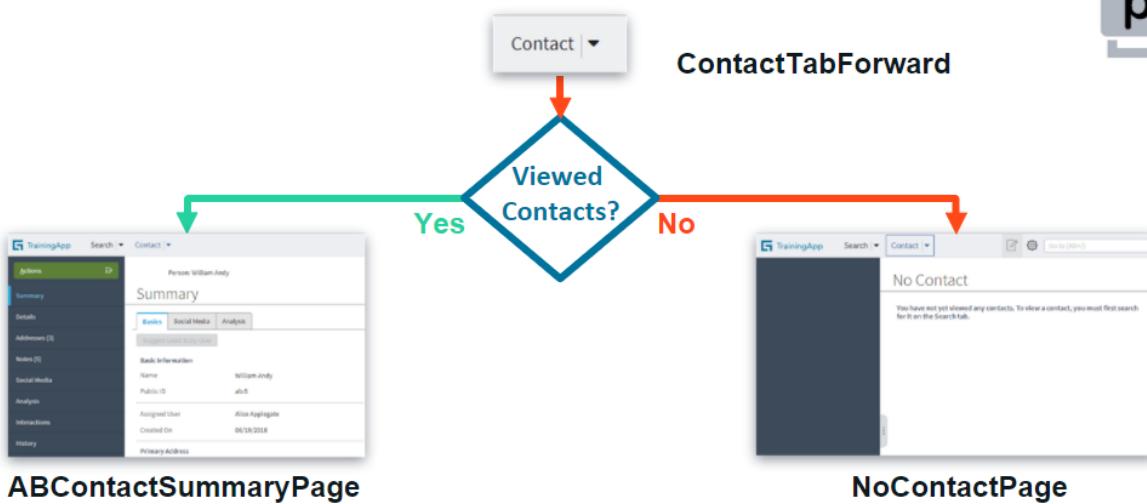

You can use forwards to:

- Modify data before navigating
- Determine the destination Location based on the data context or the user's permissions

Forwards

- A **Forward** contains logic to execute before navigating to another Location
- Often involves deciding which Location to navigate to

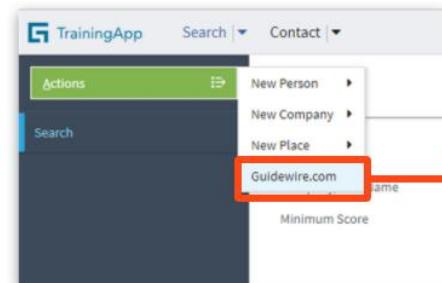

Exit points

Exit points are typically used to let users easily access other applications, such as a reporting application.

Exit points

- An **exit point** points to a URL outside of the Guidewire application
- Often used to access other applications or websites
- Does not contain (directly or indirectly) a Screen widget

Review of Locations navigation

A Page contains a single screen in the screen area.

A Popup contains a single screen and is designed to return the user to the previous Location once the work on the popup screen is complete.

A Worksheet contains a single screen and a tab (on the bottom) in the workspace frame.

A Location Group organizes a set of menu links (and their associated Locations), a set of menu actions, and an info bar into a group.

A Wizard contains multiple screens in a specific order and a toolbar to work through the wizard.

A Forward contains logic to execute before navigating to another Location.

An Exit Point points to a URL outside of the Guidewire application.

Locations summary

This table provides a summary of Location types, their typical navigation method, what they initially display, and what component of the UI the initial display is located in.
Note: In ClaimCenter and PolicyCenter, navigation to a wizard typically uses go(). In BillingCenter, navigation to a wizard typically uses push().

Locations summary

	Typical Navigation Method	Initially Displays	In
Forward	go()	Nothing	--
Location Group	go()	First child page	Screen area
Page	go()	Screen	Screen area
Wizard	go() push()	First screen	Screen area
Worksheet	goInWorkspace()	Screen	Workspace frame
Popup	push()	Screen	Originating frame
Exit Point	push()	External page or web site	New window (or entire existing window)

Of the seven types of Locations listed... Which two contain multiple screens and have their own info bar, actions menu, and side bar?

Answer

Of the seven types of Locations listed...
Which two contain multiple screens and have their own
info bar, actions menu, and side bar?

The correct response is:

Location Group and Wizard

- Locations

Guidewire Gosu

Gosu is Guidewire's open-source, publicly available programming language. Gosu has elements of both procedural and object-oriented programming languages and is similar to JavaScript and Java.

Guidewire developed Gosu for several reasons.

First, there was a desire to have a single syntax that could be used to work with all of the elements relevant to Guidewire products (such as entities, display keys, classes, class enhancements, Java classes, permissions, and script parameters) even though these items have fundamentally distinct internal implementations. There was no existing language that provided this ability.

Second, there was a desire to have code auto-complete features in Studio. This is possible only with a statically typed language. Most scripting languages, such as JavaScript, Perl, Python, and Ruby, are dynamically typed.

In very early releases of InsuranceSuite, Gosu was known as GScript.

Guidewire Gosu

- Guidewire's programming language
 - Similar to Java and compatible with Java
 - Has elements of both procedural and object-oriented programming languages
- Executes fundamental application behavior
- Manages complex business processes
- Executes hierarchical Gosu Rules
- Specifies dynamic user interface behavior

Page 4

[◀ PREV](#) [NEXT ▶](#)

Gosu in Guidewire applications (1 of 3)

A rule is a single decision in the following form of testing a condition and then taking an action: if {some conditions} then {take some action}. A rule set combines many individual rules into a useful set to consider as a group.

Gosu enhancements provide additional methods (functionality) on a Guidewire entity. For example, you can create an enhancement to the ABCContact entity. Within enhancement, you add methods that support new functionality. Guidewire Studio will show the new method for an entity of the type ABCContact.

Note: Enhancements are not limited to entities. Technically any Gosu or Java class can be enhanced.

Gosu in Guidewire applications (1 of 3)

Gosu Rules

- Apply specific programming logic for testing a condition and performing an action
- Examples:
 - Event Fired Rules
 - Pre-update Rules
 - Validation Rules

Entity Enhancements

- Extend entity functionality with programming logic as entity methods
- Examples:
 - ABCompany.maskTaxId() returns a value with a mask for the first 5 characters

Page 5

Gosu in Guidewire applications (2 of 3)

Shown here is a comparison between the use of Entity Names and Gosu Classes.

Gosu in Guidewire applications (2 of 3)

Entity Names

- Programming logic that defines how to display a name for an entity instance
- Examples:
 - Drop-down lists of contacts
 - DisplayName property of entity instance

Gosu Classes

- Encapsulate data and code for a specific purpose or function
- Examples:
 - Utility helper classes for logging or string functions
 - Plugins for integrations with other applications

Page 6

Gosu in Guidewire applications (3 of 3)

A workflow executes processes whose execution is time-based or is triggered by events in external applications or is both triggered and time-based.

Workflows are available in all three primary Guidewire applications. PolicyCenter uses workflows to manage policy transactions (such as renewals). BillingCenter uses workflows to manage account delinquency and agency bill cycles. Although the feature is available in ClaimCenter, the base configuration of ClaimCenter does not use workflows.

Gosu in Guidewire applications (3 of 3)

Workflows

- Run custom business processes asynchronously, optionally with multiple states that transition over time
- Examples:
 - Renewal and cancelation workflows

Gosu Scratchpad

Gosu Scratchpad can be used to write, execute and debug Gosu code snippets.

To open up the Gosu scratchpad, select Tools and then Gosu Scratchpad

In the example above, we run a simple Gosu query to load data from the application database. We can also execute transactions to commit test data.

The Gosu scratch pad supports common editor features

- Gutter Area
- Smart Completion
- Validation bar and
- Debugging

The Run in Debug Server process button (3) uses the Platform compiler while the Run (1) and Debug (2) buttons use the community (open source) compiler. There are a few minor differences between the two versions of Gosu, but those are out of scope for this course.

It is recommended to use the Run in Debug Process button (3) and use Platform compiler since all the applications are written using the Platform compiler.

The server must be running in debug mode (4) before you can run Gosu code using the debug server process button (3).

Gosu Scratchpad

The screenshot shows the Gosu Scratchpad interface. On the left, the Tools menu is open, highlighting 'Gosu Scratchpad Alt+Shift+S'. A red arrow points to this item. To the right, the main window displays a code editor with the following Gosu code:

```

uses trainingapp.base.QueryUtil

var contactID = "ab:5"
var anABPerson = QueryUtil.findPerson(contactID)

print(anABPerson.)

```

A red box labeled 'Gutter area' points to the left margin where numbers 1, 2, 3, and 4 are displayed above the code. A red arrow points to the number 4. Another red box labeled 'Smart completion' points to a tooltip for 'anABPerson.' showing a list of properties: FirstName, CellPhone, CellPhoneCountry, CellPhoneExtension, DateOfBirth, FirstNameKanji, FormerName, Gender, getCellPhone(), and getCellPhoneCountry(). Below the code editor, the status bar shows 'Connected to the target VM, address: '127.0.0.1:64653', transport: 'socket''. At the bottom, tabs for Run, Debug, TODO, Properties, and Terminal are visible.

Smart completion

1 Run

2 Debug

3 Run in Debug Server process

4 Run (Server) in debug mode

Configuration of Guidewire applications often focuses on working with data model entity arrays. An array defines a set of additional entities of the same type to associate with the main entity.

A related data model array is the associative array. An associative array provides a mapping between a set of keys and the values that the keys represent. A common example of this type of mapping is a telephone book, in which a name maps to a telephone number. Another common example is a dictionary, which maps terms to their definitions.

An array is a collection of data values, with each element of the array associated with a number or index.

In typical Gosu code, simply use angle brackets after the type name, such as `String[]` to represent an array of `String` objects. Use a zero-based index number to access an array member. If you create an array, you must explicitly define the size of the array or implicitly define the size by simultaneously defining the array elements. To access the elements of an array, you use an index expression.

Arrays

Data model entity array

- `<array/>` on parent entity to array entity
 - `<foreignkey/>` on array entity to parent entity
- Example**
- ABContact defines FlagEntries array

Derived API entity array

- Entity enhancement or Guidewire API
- Example**
- ABContact AllAddresses property returns an Address array

Gosu datatype and object array

- A set of values are of the same type in a single collection
- **Examples**
 - `var a = new int[3]`
 - `var b = new int[] {1,2,3}`
 - `var c : int[] = {1,2,3}`

Array methods that require logic

A variety of array methods are available in Gosu, including methods that get information about the array or that get members of the array that match a given condition.

For methods that require an argument, the argument must be an expression of a condition, such as returning *true* if any row in the array matches the condition, returning the first row matching the condition, or returning all rows that match the condition. Arguments must be in the form of a Gosu block expression.

Array methods that require logic

- Array methods include
 - Getting information about the array
 - Getting members of the array that match a given condition
 - Some methods require an argument
 - Argument must be an expression of a condition, such as:
 - Returns true if any row in the array matches the condition
 - Returns the first row that matches the condition
 - Returns all rows that match the condition
 - Argument must be a Gosu block expression

Guidewire Proprietary & Confidential – DO NOT DISTRIBUTE

Page 10

Common array methods (1 of 2)

Common array methods include `hasMatch(condition)`, which determines if any element in an array matches the condition provided, and `countWhere(condition)`, which returns a count of elements in an array that match the condition.

Common array methods (1 of 2)

- **hasMatch (condition)**
 - Determine if any element in an array matches a given condition
 - Syntax: `array.hasMatch(\ name -> conditionToMatch)`
- **countWhere (condition)**
 - Returns count of elements that match a given condition in an array
 - Syntax: `array.countWhere(\ name -> conditionToMatch)`

Common array methods (2 of 2)

Additional array methods include `firstWhere(condition)`, which retrieves the first element of an array matching the condition, and `where(condition)`, which creates a target array consisting of the members of the source array that match the condition. For a more detailed description and information on other methods, see the product documentation.

Common array methods (2 of 2)

- **`firstWhere(condition)`**
 - Retrieve the first element in an array that matches a given condition
 - Syntax: `array.firstWhere(\ name -> conditionToMatch)`
- **`where(condition)`**
 - Retrieves a target array that consists of all the members of a source array that match a given condition
 - Syntax: `array.where(\ name -> conditionToMatch)`

[◀ PREV](#) [NEXT ▶](#)

Blocks argument expression

Blocks are used in many situations where a method requires an expression as an input parameter, such as in arrays, queries, and transaction bundles for database transactions.

A block is an expression of logic passed to a method as an argument. Some array methods require conditions using a block.

The block consists of four parts:

1. \, which identifies that the following is a block
2. An element name representing each element of the array
3. ->, which identifies the start of the condition
4. A condition, which relates to the element

1 2 3

```
var notes = someNotes.where( \ note ->  
    ④ note.ContactNoteType == typekey.ContactNoteType.TC_GENERAL)
```

- A **block** is an expression of logic passed to a method as an argument
- Some array methods require conditions using a block
- The block consists of four parts:
 1. \, which identifies that the following is a block
 2. An element name representing each element of the array
 3. ->, which identifies the start of the condition
 4. A condition, which relates to the element

In the screenshot shown here, what is the array method to return the number of objects in the ContactNotes array? What is the value?

Gosu Rules

Guidewire Proprietary & Confidential – DO NOT DISTRIBUTE
© 2021 Guidewire Software, Inc. For information about Guidewire's trademarks, visit <http://guidewire.com/legal-notices>.

Page 3

[◀ PREV](#) [NEXT ▶](#)

Gosu rules

Note: Guidewire strongly recommends that you develop and document the functional logic of rules before attempting to turn that logic into rules within an InsuranceSuite product. Gosu rules require in-depth domain knowledge and technical expertise to create. After you make changes to Gosu rules, you typically need to restart the application server.

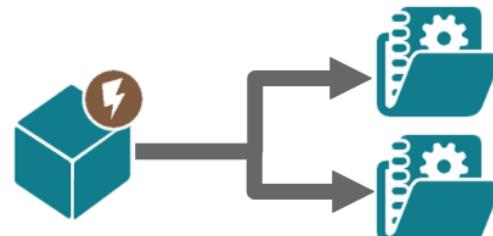

Gosu rules

- A **Rule** is a Gosu class with the file extension .gr
- A Rule is a single decision in the following form:

```
If {some conditions}  
Then {take some actions}
```

- Example:
 - If ABPerson doesn't have an email address, then create a Flag Entry to notify the TrainingApp users
 - When an Event happens to an Entity, different set of Rules might be executed by the Guidewire application
 - Example: when ABContact is saved the system runs
 - The ABContactPreupdate Rules and
 - The ABContactValidation Rules

Examples in Guidewire applications

Shown here are various examples of Gosu rules in use in InsuranceSuite applications.

Examples in Guidewire applications

- Activity escalation rules
 - Escalate activity that is open for too long
 - Triggered when activity is open past its escalation date
- Claim assignment rules
 - Assign given claim to a group and user
 - Triggered when claim is created or needs reassignment
- Account validation rules
 - Verify that account is valid before committing it to database
 - Triggered when account is created or modified

Guidewire Proprietary & Confidential – DO NOT DISTRIBUTE
© 2021 Guidewire Software, Inc. For information about Guidewire's trademarks, visit <http://guidewire.com/legal-notices>.

Page 5

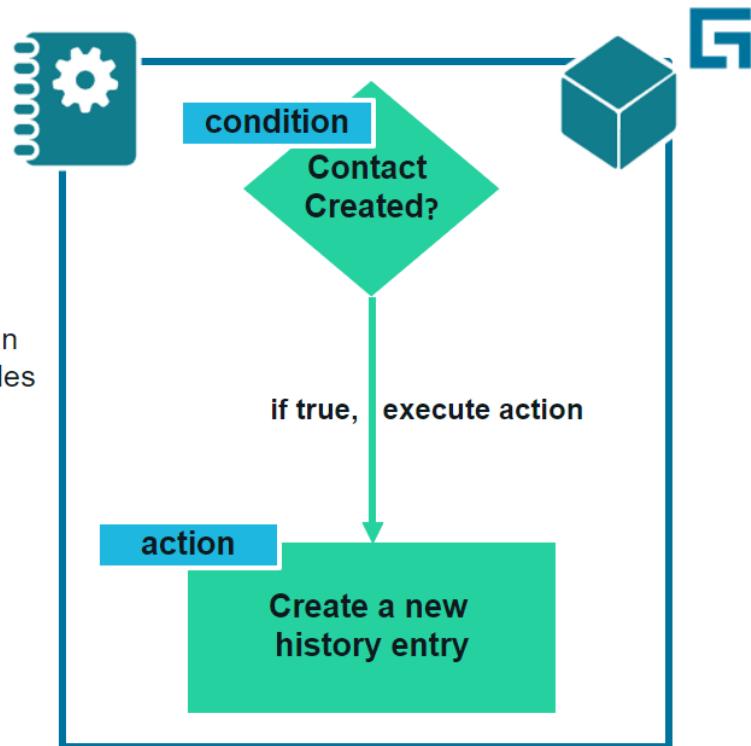

Gosu rule anatomy

Setting a rule condition to "true" means that the action will always be performed whenever the rule is evaluated.

Notice that there is no "if" in the condition. This is assumed. The only valid condition is a boolean expression.

Gosu rule anatomy

- **Root entity**
 - Input parameter for the rule
- **Name**
 - Unique and follows naming convention
 - Example: **ABPU1010 – Contact Created** is an example of a naming convention for Gosu Rules decided on by the development team
- **Condition**
 - Expression that evaluates to true or false
- **Action**
 - If condition is true, the Guidewire application executes the action
 - If condition is false, nothing happens

Page 6

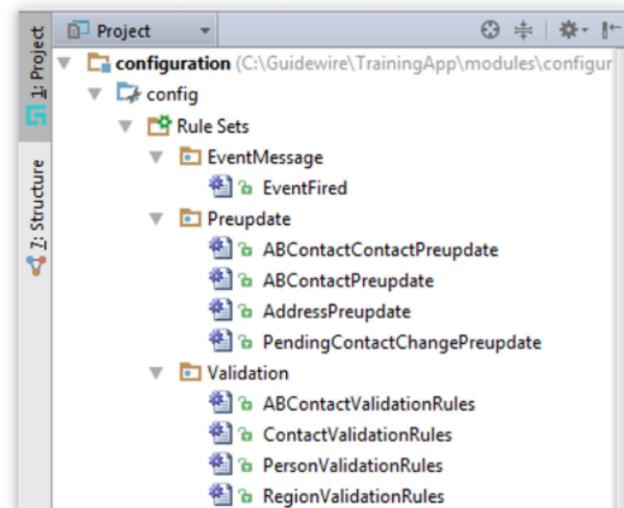

Hierarchy: Rule Set Category (1 of 2)

You can create new rule set categories. This is recommended only in the uncommon situation of an implementation that needs a new type of rule set category that is completely unlike any existing rule set category, however. To create a new rule set category, right-click the Rule Sets node and select New > Rule Set Category. You can also create a rule set category as a child node of an existing rule set category if there is a need to subgroup rule sets.

Hierarchy: Rule Set Category (1 of 2)

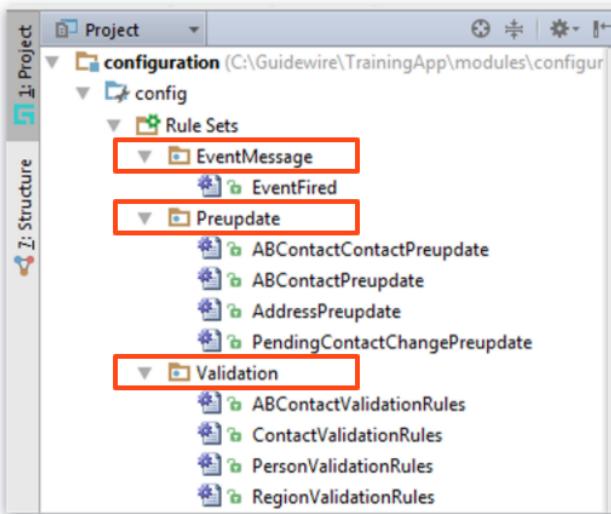

- A **Rule Set Category** is a collection of Rule Sets that have the following 2 things in common:
 - High-level business purpose
 - Trigger (Event)

Hierarchy: Rule Set Category (2 of 2)

Guidewire applications contain the triggers for event messaging, preupdate, and validation. These triggers are associated with their respective rule set categories. This is true of all Guidewire applications and not just TrainingApp. If you create a new rule set category, you must also write the code necessary to trigger the rule sets in the rule set category. For more information, consult the Rules Guide in documentation.

Hierarchy: Rule Set Category (2 of 2)

In Project View, the top-level node is Rule Sets, a misnomer. The physical folder is ...\\config\\rules\\.

- Examples:

- EventMessage

- Performs event processing and generates messages about events that have occurred
 - Triggered during save

- Preupdate

- Performs domain logic or validation that must come before committing entity
 - Triggered during save

- Validation

- Performs validation that must come before committing entity that ensures data is valid
 - Triggered during save

Guidewire Proprietary & Confidential – DO NOT DISTRIBUTE

© 2021 Guidewire Software, Inc. For information about Guidewire's trademarks, visit <http://guidewire.com/legal-notices>.

Page 9

Hierarchy: Rule Sets

You can think of a rule set as a logical grouping of rules that are specific to a business function. You organize the rules in a rule set into a hierarchy that fits your business model. In other words, a rule set combines many individual rules into a useful set to consider as a group. One way that Guidewire helps you define the organization of rules is with a root entity and common triggers. A rule set is a collection of rules that share the same root entity and share common triggers. You write code for new rule set categories to define the triggers associated with a rule set. If you create rule sets for an existing rule set category (Event Messaging, Pre-update, and Validation), you do not need write trigger code.

Execution of rules always occurs at the rule set level. Unless the rules engine encounters an exit() command, all rules in the rule set are executed.

TrainingApp is built by heavily customizing an instance of ContactManager, and therefore has the same rule sets as ContactManager. These include:

- The Event Fired rule set, which is associated with MessageContext and triggers when a MessageContext object fires an integration event

Hierarchy: Rule Sets

ABContact Preupdate (Active)

Description

This is the ABContact Preupdate rule set to permit modification of the contact and related entities. Exceptions will cause the bounding database transaction to roll back, effectively vetoing the update.

Root Entity
entity.ABContact

- A **Rule Set** combines many individual rules into a useful set to consider as a group
- A **Rule Set** defines the root entity type
 - All the Rules in the set will be attached to same the triggering entity (root entity)
- Only the Rule Set Editor exposes individual rules.

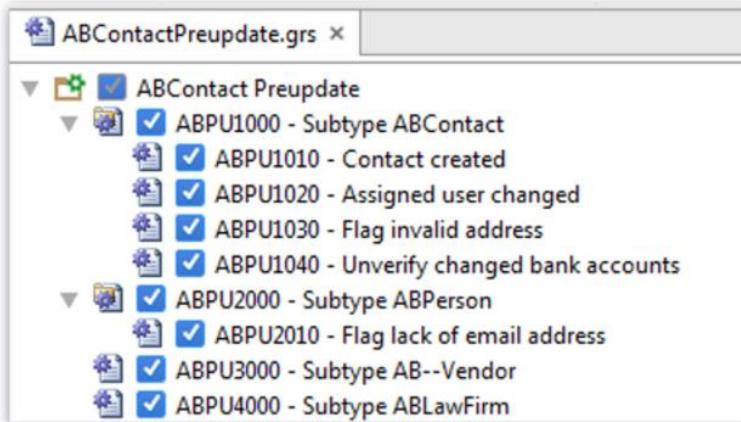

Hierarchy: Rules

If a rule has child rules, but the parent rule condition is false, neither the parent action nor the child rules are executed. In the slide example, the active (checked check box) rules are executed in the following hierarchy:

- ABPU1000 gathers together the rules relevant for all contacts. The child rules are executed only if this condition is true.
 - ABPU1010 creates a new history event when a contact is created.
 - ABPU1020 executes the necessary actions when a contact's assigned user changes (such as creating a note to record the change).
 - ABPU1030 executes the necessary actions when a flagged contact is unflagged (such as creating a note to record who unflagged the contact).
- ABPU2000 checks to see if the contact is an ABPerson. The child rules are executed only if this condition is true.
 - ABPU2010 flags any person who does not have an email address.

Hierarchy: Rules

- A **Gosu Rule** consists of a root entity, an expression that resolves to true or false, and an action that is executed if the condition is true
- Rules can have child rules
- If parent condition is true, Guidewire executes action and then executes all child rules

What is the significance of a rule set's root entity?

Answer

What is the significance of a rule set's root entity?

Every rule set is tied to an entity, known as the root entity. This determines which class of objects the rule set is tied to. It also determines the object available to the rules in the rule set when the rule set is triggered.

Gosu enhancements

Guidewire types that can be enhanced include entities, Java classes, permissions, and SOAP entities. A fundamental reason for enhancing an entity is to add behaviors to a type that would not be appropriate to do by creating a subtype.

Gosu enhancements

- Gosu enhancements allow you to augment classes and other types with additional concrete methods and properties
- The most valuable and useful uses of this feature are:
 - to add new properties and methods to Guidewire Entities. Entities are defined in XML files and source code is automatically generated, thus cannot be modified, and
 - to define additional utility methods on a Java class or interface that cannot be directly modified. For example, the source code is unavailable, or a given class is final (cannot be subclassed)
- If an Entity/Java class is enhanced, then all the subtypes/subclasses will automatically inherit all elements from the enhancement

Page 4

Enhancement components

Enhancements can have any number of the following: getters, setters, and methods.

Enhancement components

Getter properties

- Calculate derived values

Setter properties

- Take input parameters, and/or

Functions

- Set field values that require additional logic
- Modify other objects, and/or
- Create objects

Derived (virtual) properties

In the slide example, ABPersonEnhancement.gsx is the enhancement file that extends the ABPerson entity with an Age property.

Derived (virtual) properties

- ABPersonEnhancement.gsx enhances ABPerson entity and defines the Age getter property
- Property calculates age based on the date of birth value
- Derived values should NOT be stored in the database, because storing them would be redundant
 - They are calculated from physical fields

Person Info		Phone & Addresses	Bank Accounts	Employment Info	
Name				Occupation	Employer
Full Name	William Andy				Albertson's
Prefix					
First Name	William				
Middle Name					
Last Name	Andy				
Suffix					
Tax Info				Personal Statistics	
Tax ID	*****			Height	40
Tax Filing Status	Single			Age	39
Gender	Male				
Marital Status	Single				
Date of Birth	08/02/1979			Contact Insights	0
				Insight Score	

Getter property

A getter is appropriate when you can derive a value and the derived value does not need to be stored in the database. In the slide example, ABPersonEnhancement.gsx is the enhancement file that extends the ABPerson entity with an Age property.

Getter property

- A **getter property** is used to calculate a derived value
 - Property not declared at Data Model level
 - As a result the value is not stored in database
 - Code cannot receive input parameters
 - Code can only return a value and should not alter any data
 - Null safe
 - Example: **ABPerson . Age**
 - Derives value by calculating number of years between date of birth and current date
 - Returns "Unknown" if date of birth is null
 - Storing Age in database is redundant

Setter property

An implementation of any Guidewire application will have a small number of setters because of the limiting criteria for use. A setter is appropriate only when you need to set one or more fields based on a single input value and—if there is a single field to be set—it is a field that cannot be set by simply assigning the input value to the field.

Possible use cases for setters could include:

- Adding a value to one field out of several possible fields (such as adding a new phone number to either Work Phone, Home Phone, or Cell Phone).
- Adding an object to an array and making that value the primary object (such as adding a new employee to an ABCCompany and making that employee the primary contact).
- Adding a value to a field that must be converted to a different unit (such as receiving a dollar amount in Euros but needing to store that amount as dollars).
- Converting an integer value to a typekey value (such as receiving an integer that represents the number of employees and using that to set a CompanySize typekey value which could be: Under 100, 101 to 500, ...)

Setter property

- A **setter property** takes a single input value and uses it to modify the associated object
 - Property not declared at data model level
 - Value given to setter may or may not be stored in database
 - Value manipulated by setter is typically stored in database
 - Code must receive exactly one input parameter
 - Should not be used to alter other objects
- Example: **ABPolicyPerson.HeightInInches (arg)**
 - Getter takes height from database (in meters) and converts it to inches (so, for example, it can be displayed in UI)
 - Setter takes height (in inches) and converts it to meters before saving it to database

Page 8

Gosu enhancements for Java

Gosu enhancements provide additional methods (functionality) on a Guidewire entity. For example, suppose that you create an enhancement to the Activity entity. Within this enhancement, you add methods that support new functionality. Then, if you type Activity. (Activity dot) within any Gosu code, Studio automatically uses code completion on the Activity entity. It also automatically displays any methods that you have defined in your Activity enhancement, along with the native Activity entity methods.

Gosu enhancements for Java

- Write Gosu enhancements for Java types
- Useful when creating generic methods that...
 - Do NOT relate to a specific entity
 - Extend the functionality of a base data type
- Examples:
 - GWBaseIntegerEnhancement enhances `java.lang.Integer`
 - GWBaseDateEnhancement enhances `java.util.Date`
 - GWBaseListEnhancement enhances `java.util.List`
- Java enhancements typically contain static functions
- Deploy and debug the same way as other enhancements

What type of logic does a getter implement? A setter? A method?

Answer

-- What type of logic does a getter implement? A setter? A method?

The correct responses are:

Getter: Logic that returns a derived value and does not take parameters or change other data.

Setter: Logic that takes a single input value and uses that to modify some other field or set of fields on the given object.

Method: Logic that requires parameters, changes data, or otherwise does more than simply deriving or setting a value.

Page 4

[◀ PREV](#) [NEXT ▶](#)

Pattern matching

Validation is a general application behavior that prevents a user from saving invalid business data. Field-level validation is a validation behavior tied to one or more specific data fields.

A regular expression defines a pattern. The save is not allowed if the data entered by the user doesn't match the pattern.

Input masks both display a watermark in the field and guide the user to input the correct format of data. An input mask does not restrict data commit, but it does guide the user to input the data in a certain format.

Pattern matching

- Pattern matching is a field-level validation technique
- Verifies that the user entered the data in the correct format for that field
 - E.g.: tax id must be a nine-digit number with hyphens after the third and fifth digits
 - Prevents the user from saving invalid business data
- Could be implemented in the data model or the UI tier
- Main components:
 - Regular expression
 - Input mask (optional)

Guidewire Proprietary & Confidential – DO NOT DISTRIBUTE

Page 5

[◀ PREV](#) [NEXT ▶](#)

Pattern matching - regular expressions

The pattern for the Email validator is:

- Any non-empty string, specified as: .+
- An "at" symbol, specified as: @
- Any non-empty string, specified as: .+
- A period, specified as: \.
- Any non-empty string, specified as: .+

Characters that are not treated as literals and must be escaped include: [] () {} . * + ?

For a complete listing of syntax for validator patterns, consult the Configuration Guide for your product.

Pattern matching - regular expressions

- A regular expression defines an abstract pattern
- Examples:
 - Email address: .+@.+\.\.+
 - Routing number: [0-9a-zA-Z]{3}-[0-9]{3}

Details

Validation errors on current page:

Routing Number : Must be 3 alphanumerics, a hyphen, and 3 digits.

Page 6

◀ PREV NEXT ▶

Pattern matching – input masks

Input masks and regular expressions guide the user input for the field. Client-side regular expressions notify the user of an issue with the field input when a placeholder character (#) is used in the inputMask expression. An input mask identifies to the user the specific form of the data to enter into a given field. Typically, an input mask shows a basic pattern for a field. Input masks can also guide the user to input a specific character input in the field.

When an input mask contains placeholders (e.g., #) but does not specify either a regex property or does not have an associated entity field validator, the framework generates an implicit regular expression based on the inputMask property definition. As the user types in the field, the implicit regex triggers client-side validation, but does not restrict data commit. Instead, it guides the user to input the data in a certain format. In the example above, the field value should be 5 characters in length, the first two being upper case letters and the last three being numbers.

It should be noted that in addition to placeholders (#) in an inputMask property expression, you can force certain characters to be in the data. For example, "AB ###" forces the field to have the upper-case letters A and B to be the first two characters in the entry.

Pattern matching – input masks

- Appears as a watermark in field and mouse over tooltip
 - Changes to a darker color with data entry
 - No format warning
 - Does not restrict data commit but instead guides the user to input the data in a certain format

The screenshot illustrates the configuration and application of an input mask. At the top, a configuration panel shows the following properties:

inputMask	##-###
inputConversion	"##-##"
inputMask	"##-##"
labelAbove	False

Below this, two examples demonstrate the input mask's effect:

- Example 1:** A field labeled "License" contains "##-##". A red arrow points to the "##-##" placeholder in the input field, indicating it serves as a watermark.
- Example 2:** A field labeled "License" contains "AB-123". A red arrow points to the "AB-123" value, showing that the input mask has guided the user to enter the data in the correct format.

At the bottom, a validation error message is displayed:

Validation errors on current page:
1 License : The value in this field is invalid

Pattern matching- practices comparison

Shown here are the pros and cons and pattern matching in the Data Model and the User Interface.

Pattern matching- practices comparison

Data model

- Pros
 - Application enforces compliance in the UI and through API
 - Supports full localization
 - Robust extensibility
- Cons
 - Static values only: regex and input mask cannot change based on business logic
 - Implemented as a reusable field validator

User interface

- Pros
 - Dynamic values: regex and input mask can change based on business logic
 - Can restrict data commit
- Cons
 - Only a few widget support it
 - Must be configured per widget
 - No custom error message option
 - Extensibility a big concern
- Implemented as widget properties

Example: pattern matching in the UI

PCF Format Reference:
<application-installation-folder>/modulespcf.html

Example: pattern matching in the UI

- Implementing the user story in the UI requires duplicating regex and input mask
- **inputMask** and **regex** properties can be dynamic
 - To improve the design, a function call could be used instead of hard-coding the strings
- No custom error message
- Not all the widgets have the **regex** and **inputMask** properties
 - Refer to PCF Format Reference

The screenshot shows two PCF configuration screens side-by-side:

- PolicyPopup.pcf**: A detail view form with a single text input field. The properties panel shows:
 - inputConversion
 - inputMask: `"##-#####"`
 - labelAbove: `false`
 - labelStyleClass
 - maxChars
 - numCols
 - numEntriesPerColumn
 - gnPick
 - outputConversion
 - regex: `"[A-Z]{2}-[0-9]{7}"`
- PolicyLV.pcf**: A list view form with a row editor. The properties panel shows:
 - Policy Number: `currentPolicy..`
 - Premium: `$currentPolicy..`
 - Location: `currentPolicy.PolicyLocation`
 - Page Configuration: `Text`
 - Properties: `Properties`, `Layout config`, `Reflection`
 - Text Cell:
 - inputMask: `"##-#####"`
 - labelStyleClass
 - maxChars
 - numEntries
 - numEntriesPerColumn
 - gnPick
 - outputConversion
 - printWidth
 - regex: `"[A-Z]{2}-[0-9]{7}"`

Page 9

Script parameters

- A **script parameter** is an application-wide global constant
 - Value maintained by administrator
 - Can be referenced in any Gosu code
 - Typically used for values that may change over time and therefore should not be hard-coded

The screenshot shows a user interface with two main sections: 'Additional Info' on the left and a modal window titled 'Details' on the right.

Additional Info:

- Tax ID: *****
- Inspection Required?: No
- Preferred Currency: <none selected>
- Collateral Info:**
- Collateral Required?: Yes
- Collateral Amount: 4000
- Collateral Verified?: <none selected>

Details Modal:

Collateral Amount : Collateral must be at least 5000

Update Cancel

Red boxes highlight the 'Collateral Amount' field (containing '4000') and the validation message in the 'Details' modal (containing 'Collateral must be at least 5000'). Red arrows point from these highlighted areas to the corresponding text in the list below.

Examples from base applications

Script Parameters		BillingCenter	
Script Parameters		Script Parameters	
Name ↑	Type	ClaimCenter	
LegacyAgencyBillPlan	java.lang.Object	InitialReserve_AutoGlassVehicleDamage	java.lang.Integer

About Partial Page Update

This section discusses partial page update.

About Partial Page Update

Guidewire Proprietary & Confidential – DO NOT DISTRIBUTE

© 2021 Guidewire Software, Inc. For information about Guidewire's trademarks, visit <http://guidewire.com/legal-notices>.

Partial page update: Layout re-render

In the slide example, the Company Info card has both an Inspection Required field and Inspection Date field. However, the Inspection Date field is visible only if the Inspection Required? field is set to Yes.

The InspectionRequired widget displays a Yes or No radial button. A selected Yes radial button equates to true and a selected No radial button equates to false. A null value is represented as neither radial button selected.

Dynamic widget behavior differs from a property that evaluates an expression in that the user changes the business data while editing it and that change affects the behavior of the widget. In the previous examples, the changes are present only after the data has been committed.

Partial page update: Layout re-render

- Responds to a user changing business data **while** it happens and changes the layout of widgets on the screen
- Example:
 - While a user changes the Did agent inspect vehicles? field to Yes, a secondary question and the Date Input widget becomes visible

The screenshot shows two states of a 'Qualification' form. In the first state, the 'Did agent inspect vehicles?' field has a 'No' radio button selected. In the second state, the 'Yes' radio button is selected, and a red arrow points from this change to the 'When was the inspection?' field, which is now displayed and contains a date input field ('MM/dd/yyyy').

Guidewire Proprietary & Confidential – DO NOT DISTRIBUTE
© 2021 Guidewire Software, Inc. For information about Guidewire's trademarks, visit <http://guidewire.com/legal-notices>.

Page 10

[PREV](#) [NEXT](#)

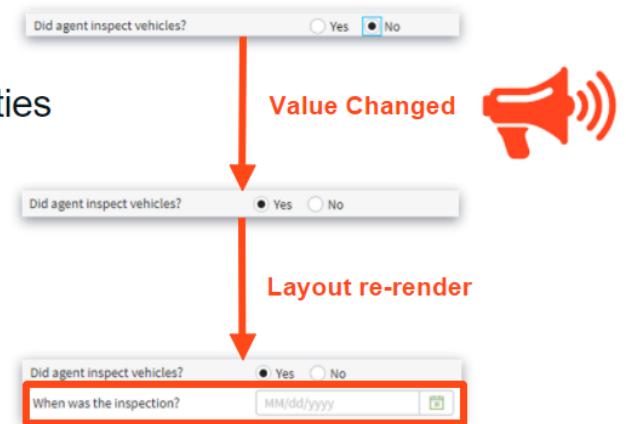

Partial page update: Layout re-render (Continued)

There are two general and non-exclusive categories for a partial page update: layout re-render and DATA_ONLY.

In the layout re-render example above, whenever the value of the InspectionRequired field is changed, all user editable data is sent from the client to the application server. No data is committed. The application server processes the request and returns instructions and user editable data to the client. The client re-renders the layout that shows an Inspection Date field.

Partial page update: Layout re-render (Continued)

- Layout re-rendered for the page
- No data committed
- Applies to following dynamic widget properties
 - visible
 - editable
 - available
 - required

Partial page update: DATA_ONLY

In the DATA_ONLY example, the widget configuration enables dynamic widget behavior for the Affinity Group name TextInput widget. When a user changes the value of the Name field, the client makes a request to the application server. The application server processes the request and returns instructions to the client. In this case, the instructions tell the client to render only the newly supplied data for the Business and Operations fields (year started and description of business)

Partial page update: DATA_ONLY

- Responds to a user changing business data **while** it happens
 - Not after the user navigates to the page
 - Not after the user commits or tries to commit the data
- Example:
 - While a user changes the Affinity Group Name field, values for other fields are rendered with changes (read-only in UI)

The figure consists of two side-by-side screenshots of a business form. Both screenshots show the same set of fields: County (San Mateo), Address Type (Home), Address Description (Created by the Address Builder with code 0), Official IDs, SSN (342-56-8729), Industry Code (0740), Business and Operations (Year Business Started: 1967, Description of business and operations: 'business description'), and Underwriting Companies (Acme Low Hazard Insurance). The top screenshot shows the 'Base State' dropdown set to 'California'. The bottom screenshot shows the 'Name' field of the 'Affinity Group' section changed to 'Bellingham'. Red arrows highlight the 'Name' field in the top screenshot, the 'Base State' dropdown in the bottom screenshot, and the 'Year Business Started' field in the bottom screenshot, illustrating how changes in one field trigger updates to other fields.

Two kinds of widget properties

In the slide example, the id property of a widget is a static property. The widget always has the same ID, regardless of the state of the application or the values of any business data. The property does not evaluate an expression, just the value of a type, such as a String or Integer value.

The editable property evaluates a boolean expression and the expression can be a dynamic value, in this case, one that returns true or false. The label property evaluates a string expression. This lesson discusses display keys later on. Display keys are a type of string expression Guidewire applications for localizing text. The value property is also a dynamic property. The value property evaluates an object expression that binds the object property to it.

Both types of widget properties can be required properties for a specific type of widget.

Two kinds of widget properties

Static Property

- Evaluates a static value that is immutable, never changes
 - id requires a static value

Dynamic Property

- After a user navigates to a page or clicks update, evaluates an expression and returns a value
 - editable requires boolean expression
 - label returns a string expression
 - value returns an object expression

Properties:	
	Properties
Text Input	Layout config
Basic properties	Reflection
editable	true
id*	FirstName
label	DisplayKey.get("Training.FirstName")
required	
value*	(anABCContact as ABPerson).FirstName

Guidewire Proprietary & Confidential – DO NOT DISTRIBUTE
© 2021 Guidewire Software, Inc. For information about Guidewire's trademarks, visit <http://guidewire.com/legal-notices>.

Page 4

◀ PREV NEXT ▶

Dynamic properties evaluate expressions

Not all widgets have all properties. Refer to the PCF Format Reference for more examples. Recall that the PCF Format Reference defines the properties for every widget, including the type of value the property takes. Note that the PCF Format Reference refers to widget properties as "attributes". To open the PCF Format Reference, open <ApplicationRootDirectory>\modules\pcf.htm file in your web browser.

You can also consider the value property of a widget to be a dynamic property because it evaluates an object expression.

Visible is typically not set to false. It is either set to true or it is set to an expression that renders the widget visible or not visible. The default value for the visible property is true.

Dynamic properties evaluate expressions

- Available
 - Boolean expression which, if false, grays out the widget and its children
- Editable
 - Boolean expression which, if false, makes the widget and its children read-only
- Required
 - Boolean expression which, if true, then a value must be filled out by the user
- Visible
 - Boolean expression which, if false, completely hides the widget and its children

Guidewire Proprietary & Confidential – DO NOT DISTRIBUTE
© 2021 Guidewire Software, Inc. For information about Guidewire's trademarks, visit <http://guidewire.com/legal-notices>.

Page 5

[◀ PREV](#) [NEXT ▶](#)

Notes

Post On Change properties

In certain cases, you may want to toggle (disable or enable) targeted Post On Change behavior for a specific widget.

In the slide example, the Invoicing Method field will disable Post On Change if the currency is not USD.

For all other currencies, the Post On Change will be disabled. The widget will not announce a change in its value; data will not make a round-trip between client and the application server; the page will not be re-rendered and data won't be refreshed.

In the slide example, the Gosu expression defined for the onChange property invokes the setFieldsOnResolution() function. The function is defined in the entity enhancement, FlagEntryEnhancement.gsx.

```
16 /* This function is called when
a FlagEntry's resolution field
17 is set. This function sets the
UnflagDate and UnflagUser
18 fields. This serves the role of a
"FlagEntry Pre-Update"
19 rule set.
20 */
21 function
setFieldsOnResolution(): void {
22 this.UnflagDate =
gw.api.util.DateUtil.currentTimeMillis()
23 this.UnflagUser =
User.util.getCurrentUser()
24 } // end of function
```

Post On Change properties

disablePostOnEnter

- If evaluated true when page is rendered, this field won't trigger Post On Change
- Default is false

Invoicing Method aPolicy.InvoicingMethod ▾

Page Configuration	Text

Page 15

Target property (earlier versions)

When specified as a widget, the target area can be a specific widget or a grouping of widgets. For example, if the Widget ID corresponds to an Input Set, then the widgets in the input set are re-rendered.

There is an additional layout re-render configuration for backwards compatibility: no value. The no value configuration consists of enabling targeted post on change alone with no property configurations. The backwards compatibility configuration has no property values specified and causes the re-rendering of the entire page and refreshes all user-editable data. There is a high-performance cost for implementing targeted Post On Change without specifying a target and any other properties.

In current InsuranceSuite applications, targeted update is automatic for any widget where Targeted Post On Change is enabled, and the target property is redundant.

Target property (earlier versions)

Layout re-render

- Widget ID
- Target area re-rendered
- All editable data refreshed
- Widgets can also be grouped and parent container can be targeted

Data update

- DATA_ONLY
- No layout re-render
- All editable data refreshed
- Better performance

Page 16

Answer

-- Name two properties that evaluate expressions.

Possible answers include:

- editable
- required
- visible
- available

How is a partial page update implemented?

Answer

-- How is a partial page update implemented?

A partial page update is implemented by configuring dynamic widget behavior by enabling targeted post on change. Often the dynamic widget behavior configuration also includes configuring an expression for a widget property.

[◀ PREV](#) [NEXT ▶](#)

Guidewire Gosu

Gosu is Guidewire's open-source, publicly available programming language. Gosu has elements of both procedural and object-oriented programming languages and is similar to JavaScript and Java.

Guidewire developed Gosu for several reasons.

First, there was a desire to have a single syntax that could be used to work with all of the elements relevant to Guidewire products (such as entities, display keys, classes, class enhancements, Java classes, permissions, and script parameters) even though these items have fundamentally distinct internal implementations. There was no existing language that provided this ability.

Second, there was a desire to have code auto-complete features in Studio. This is possible only with a statically typed language. Most scripting languages, such as JavaScript, Perl, Python, and Ruby, are dynamically typed.

In very early releases of InsuranceSuite, Gosu was known as GScript.

Guidewire Gosu

- Guidewire's programming language
 - Similar to Java and compatible with Java
 - Has elements of both procedural and object-oriented programming languages
- Executes fundamental application behavior
- Manages complex business processes
- Executes hierarchical Gosu Rules
- Specifies dynamic user interface behavior

[◀ PREV](#) [NEXT ▶](#)

Gosu in Guidewire applications (1 of 3)

A rule is a single decision in the following form of testing a condition and then taking an action: if {some conditions} then {take some action}. A rule set combines many individual rules into a useful set to consider as a group.

Gosu enhancements provide additional methods (functionality) on a Guidewire entity. For example, you can create an enhancement to the ABCContact entity. Within enhancement, you add methods that support new functionality. Guidewire Studio will show the new method for an entity of the type ABCContact.

Note: Enhancements are not limited to entities. Technically any Gosu or Java class can be enhanced.

Gosu in Guidewire applications (1 of 3)

Gosu Rules

- Apply specific programming logic for testing a condition and performing an action
- Examples:
 - Event Fired Rules
 - Pre-update Rules
 - Validation Rules

Entity Enhancements

- Extend entity functionality with programming logic as entity methods
- Examples:
 - ABCompany.maskTaxId() returns a value with a mask for the first 5 characters

Guidewire Proprietary & Confidential – DO NOT DISTRIBUTE
© 2021 Guidewire Software, Inc. For information about Guidewire's trademarks, visit <http://guidewire.com/legal-notices>.

Page 5

Gosu in Guidewire applications (2 of 3)

Shown here is a comparison between the use of Entity Names and Gosu Classes.

Gosu in Guidewire applications (2 of 3)

Entity Names

- Programming logic that defines how to display a name for an entity instance
- Examples:
 - Drop-down lists of contacts
 - DisplayName property of entity instance

Gosu Classes

- Encapsulate data and code for a specific purpose or function
- Examples:
 - Utility helper classes for logging or string functions
 - Plugins for integrations with other applications

Guidewire Proprietary & Confidential – DO NOT DISTRIBUTE
© 2021 Guidewire Software, Inc. For information about Guidewire's trademarks, visit <http://guidewire.com/legal-notices>.

Page 6

Gosu in Guidewire applications (3 of 3)

A workflow executes processes whose execution is time-based or is triggered by events in external applications or is both triggered and time-based.

Workflows are available in all three primary Guidewire applications. PolicyCenter uses workflows to manage policy transactions (such as renewals). BillingCenter uses workflows to manage account delinquency and agency bill cycles. Although the feature is available in ClaimCenter, the base configuration of ClaimCenter does not use workflows.

Gosu in Guidewire applications (3 of 3)

Workflows

- Run custom business processes asynchronously, optionally with multiple states that transition over time
- Examples:
 - Renewal and cancelation workflows

Gosu Scratchpad

Gosu Scratchpad can be used to write, execute and debug Gosu code snippets.

To open up the Gosu scratchpad, select Tools and then Gosu Scratchpad

In the example above, we run a simple Gosu query to load data from the application database. We can also execute transactions to commit test data.

The Gosu scratch pad supports common editor features

- Gutter Area
- Smart Completion
- Validation bar and
- Debugging

The Run in Debug Server process button (3) uses the Platform compiler while the Run (1) and Debug (2) buttons use the community (open source) compiler. There are a few minor differences between the two versions of Gosu, but those are out of scope for this course.

It is recommended to use the Run in Debug Process button (3) and use Platform compiler since all the applications are written using the Platform compiler.

The server must be running in debug mode (4) before you can run Gosu code using the debug server process button (3).

Gosu Scratchpad

The screenshot shows the Gosu Scratchpad interface. On the left, the Tools menu is open, highlighting 'Gosu Scratchpad Alt+Shift+S'. A red arrow points to this item. To the right, the main workspace shows a code editor with the following snippet:

```

uses trainingapp.base.QueryUtil

var contactID = "ab:5"
var anABPerson = QueryUtil.findPerson(contactID)

print(anABPerson.)

```

A red box labeled 'Gutter area' points to the left margin where numbers 1, 2, 3, and 4 are displayed above the code. A red arrow points to number 4. Another red box labeled 'Smart completion' points to a tooltip for 'anABPerson.' showing a list of properties: FirstName, CellPhone, CellPhoneCountry, CellPhoneExtension, DateOfBirth, FirstNameKanji, FormerName, Gender, getCellPhone(), and getCellPhoneCountry(). A red box labeled 'Debugging' points to the bottom toolbar where the 'Run' button is highlighted. The bottom status bar shows 'Connected to the target VM, address: '127.0.0.1:64653', transport: 'socket''.

Smart completion

1 Run

2 Debug

3 Run in Debug Server process

4 Run (Server) in debug mode

Configuration of Guidewire applications often focuses on working with data model entity arrays. An array defines a set of additional entities of the same type to associate with the main entity.

A related data model array is the associative array. An associative array provides a mapping between a set of keys and the values that the keys represent. A common example of this type of mapping is a telephone book, in which a name maps to a telephone number. Another common example is a dictionary, which maps terms to their definitions.

An array is a collection of data values, with each element of the array associated with a number or index.

In typical Gosu code, simply use angle brackets after the type name, such as `String[]` to represent an array of `String` objects. Use a zero-based index number to access an array member. If you create an array, you must explicitly define the size of the array or implicitly define the size by simultaneously defining the array elements. To access the elements of an array, you use an index expression.

Arrays

Data model entity array

- `<array/>` on parent entity to array entity
 - `<foreignkey/>` on array entity to parent entity
- Example**
- ABContact defines FlagEntries array

Derived API entity array

- Entity enhancement or Guidewire API
- Example**
- ABContact AllAddresses property returns an Address array

Gosu datatype and object array

- A set of values are of the same type in a single collection
- **Examples**
 - `var a = new int[3]`
 - `var b = new int[] {1,2,3}`
 - `var c : int[] = {1,2,3}`

Array methods that require logic

A variety of array methods are available in Gosu, including methods that get information about the array or that get members of the array that match a given condition.

For methods that require an argument, the argument must be an expression of a condition, such as returning *true* if any row in the array matches the condition, returning the first row matching the condition, or returning all rows that match the condition. Arguments must be in the form of a Gosu block expression.

Array methods that require logic

- Array methods include
 - Getting information about the array
 - Getting members of the array that match a given condition
 - Some methods require an argument
 - Argument must be an expression of a condition, such as:
 - Returns true if any row in the array matches the condition
 - Returns the first row that matches the condition
 - Returns all rows that match the condition
 - Argument must be a Gosu block expression

Guidewire Proprietary & Confidential – DO NOT DISTRIBUTE

Page 10

Common array methods (1 of 2)

Common array methods include `hasMatch(condition)`, which determines if any element in an array matches the condition provided, and `countWhere(condition)`, which returns a count of elements in an array that match the condition.

Common array methods (1 of 2)

- **hasMatch (condition)**
 - Determine if any element in an array matches a given condition
 - Syntax: `array.hasMatch(\ name -> conditionToMatch)`
- **countWhere (condition)**
 - Returns count of elements that match a given condition in an array
 - Syntax: `array.countWhere(\ name -> conditionToMatch)`

Common array methods (2 of 2)

Additional array methods include `firstWhere(condition)`, which retrieves the first element of an array matching the condition, and `where(condition)`, which creates a target array consisting of the members of the source array that match the condition. For a more detailed description and information on other methods, see the product documentation.

Common array methods (2 of 2)

- **`firstWhere(condition)`**
 - Retrieve the first element in an array that matches a given condition
 - Syntax: `array.firstWhere(\ name -> conditionToMatch)`
- **`where(condition)`**
 - Retrieves a target array that consists of all the members of a source array that match a given condition
 - Syntax: `array.where(\ name -> conditionToMatch)`

[◀ PREV](#) [NEXT ▶](#)

Blocks argument expression

Blocks are used in many situations where a method requires an expression as an input parameter, such as in arrays, queries, and transaction bundles for database transactions.

A block is an expression of logic passed to a method as an argument. Some array methods require conditions using a block.

The block consists of four parts:

1. \, which identifies that the following is a block
2. An element name representing each element of the array
3. ->, which identifies the start of the condition
4. A condition, which relates to the element

1 2 3

```
var notes = someNotes.where( \ note ->  
    ④ note.ContactNoteType == typekey.ContactNoteType.TC_GENERAL)
```

- A **block** is an expression of logic passed to a method as an argument
- Some array methods require conditions using a block
- The block consists of four parts:
 1. \, which identifies that the following is a block
 2. An element name representing each element of the array
 3. ->, which identifies the start of the condition
 4. A condition, which relates to the element

In the screenshot shown here, what is the array method to return the number of objects in the ContactNotes array? What is the value?

Answer

-- In the screenshot shown here, what is the array method to return the number of objects in the ContactNotes array? What is the value?

Contact Note	Contact Note Type	Subject
2018-06-19: William Andy has many general qu...	General	William Andy has questions
2018-06-19: William Andy has a new phone number	Update Contact Data	New phone number
2018-06-19: William Andy has more questions ...	General	William Andy has an inquiry
2018-06-19: William Andy sent in his new lic...	License / Certification	William Andy has a new licence
2018-06-19: William Andy has discovered a se...	Problem	William Andy reported an issue

var count = array.length or array.Count.

The total number of elements in the ContactNotes array is 5.

In the screenshot shown here, what is the expression to return the count of notes that are regarding a problem? What is the count value?

Answer

-- In the screenshot shown here, what is the expression to return the count of notes that are regarding a problem? What is the count value?

The screenshot shows a web-based application interface for 'TrainingApp'. At the top, there's a navigation bar with the 'TrainingApp' logo, a search bar, and a contact dropdown. The main area is titled 'Person: William Andy'. On the left, there's a sidebar with links: 'Actions', 'Summary', 'Details', 'Addresses (3)', 'Notes (5)', and 'Social Media'. The 'Notes (5)' link is highlighted with a blue background. Below the sidebar, the word 'Notes' is displayed. To the right, there's a table listing five contact notes. The columns are 'Contact Note', 'Contact Note Type', and 'Subject'. The notes are:

Contact Note	Contact Note Type	Subject
2018-06-19: William Andy has many general qu...	General	William Andy has questions
2018-06-19: William Andy has a new phone number	Update Contact Data	New phone number
2018-06-19: William Andy has more questions ...	General	William Andy has an inquiry
2018-06-19: William Andy sent in his new lic...	License / Certification	William Andy has a new licence
2018-06-19: William Andy has discovered a se...	Problem	William Andy reported an issue

```
var countNotes = notes.countWhere( \ note ->
note.ContactNoteType == typekey.ContactNoteType.TC_PROBLEM)
The total number of elements in the ContactNotes array is 1.
```

In the screenshot shown here, what is an expression to return an array of ContactNotes where the note was created after January 31, 2014?

Answer

In the screenshot shown here, what is an expression to return an array of ContactNotes where the note was created after January 31, 2014?

The screenshot shows a web-based application interface for 'TrainingApp'. At the top, there's a navigation bar with a 'G' logo, 'TrainingApp', 'Search', and 'Contact' dropdowns. On the left, a sidebar has tabs for 'Actions', 'Summary', 'Details', 'Addresses (3)', 'Notes (5)' (which is selected and highlighted in blue), and 'Social Media'. The main content area is titled 'Person: William Andy' and shows a 'Notes' section. Below it is a table with columns for 'Contact Note', 'Contact Note Type', and 'Subject'. The table contains six rows of data, each representing a note created on June 19, 2018. The notes are: 'William Andy has many general qu...', 'General', 'William Andy has questions'; 'William Andy has a new phone number', 'Update Contact Data', 'New phone number'; 'William Andy has more questions ...', 'General', 'William Andy has an inquiry'; 'William Andy sent in his new lic...', 'License / Certification', 'William Andy has a new licence'; and 'William Andy has discovered a se...', 'Problem', 'William Andy reported an issue'.

Contact Note	Contact Note Type	Subject
2018-06-19: William Andy has many general qu...	General	William Andy has questions
2018-06-19: William Andy has a new phone number	Update Contact Data	New phone number
2018-06-19: William Andy has more questions ...	General	William Andy has an inquiry
2018-06-19: William Andy sent in his new lic...	License / Certification	William Andy has a new licence
2018-06-19: William Andy has discovered a se...	Problem	William Andy reported an issue

```
var filteredNotes = notes.where( \ note -> note.CreateTime >= "02/01/2014".toDate() )
```

Page 3

[◀ PREV](#) [NEXT ▶](#)

Gosu rules

Note: Guidewire strongly recommends that you develop and document the functional logic of rules before attempting to turn that logic into rules within an InsuranceSuite product. Gosu rules require in-depth domain knowledge and technical expertise to create. After you make changes to Gosu rules, you typically need to restart the application server.

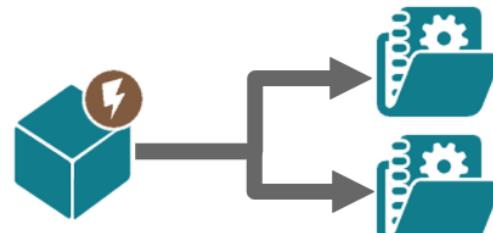

Gosu rules

- A **Rule** is a Gosu class with the file extension .gr
- A Rule is a single decision in the following form:

```
If {some conditions}  
Then {take some actions}
```

- Example:
 - If ABPerson doesn't have an email address, then create a Flag Entry to notify the TrainingApp users
 - When an Event happens to an Entity, different set of Rules might be executed by the Guidewire application
 - Example: when ABContact is saved the system runs
 - The ABContactPreupdate Rules and
 - The ABContactValidation Rules

Page 4

Examples in Guidewire applications

Shown here are various examples of Gosu rules in use in InsuranceSuite applications.

Examples in Guidewire applications

- Activity escalation rules
 - Escalate activity that is open for too long
 - Triggered when activity is open past its escalation date
- Claim assignment rules
 - Assign given claim to a group and user
 - Triggered when claim is created or needs reassignment
- Account validation rules
 - Verify that account is valid before committing it to database
 - Triggered when account is created or modified

Guidewire Proprietary & Confidential – DO NOT DISTRIBUTE
© 2021 Guidewire Software, Inc. For information about Guidewire's trademarks, visit <http://guidewire.com/legal-notices>.

Page 5

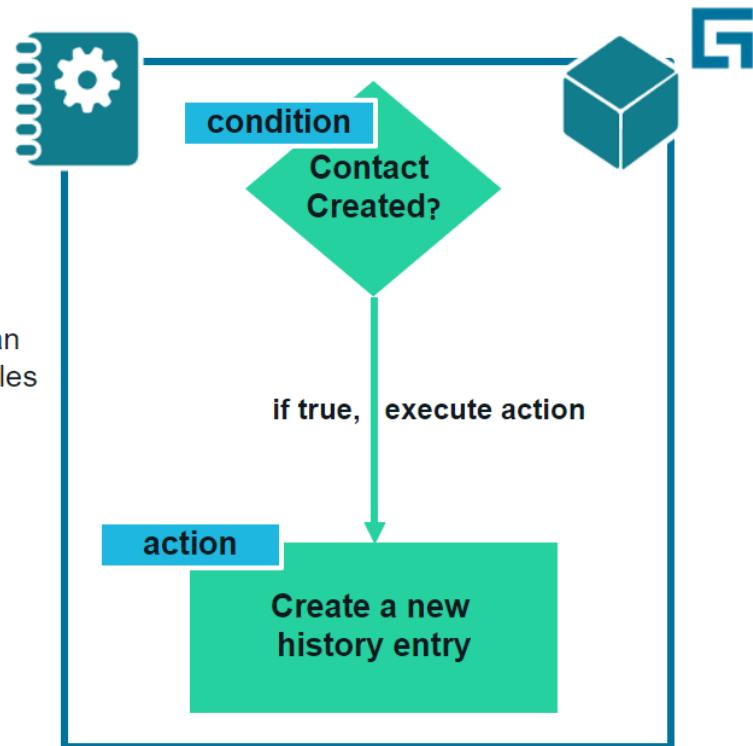

Gosu rule anatomy

Setting a rule condition to "true" means that the action will always be performed whenever the rule is evaluated.

Notice that there is no "if" in the condition. This is assumed. The only valid condition is a boolean expression.

Gosu rule anatomy

- **Root entity**
 - Input parameter for the rule
- **Name**
 - Unique and follows naming convention
 - Example: **ABPU1010 – Contact Created** is an example of a naming convention for Gosu Rules decided on by the development team
- **Condition**
 - Expression that evaluates to true or false
- **Action**
 - If condition is true, the Guidewire application executes the action
 - If condition is false, nothing happens

 Education

Page 6

Hierarchy: Rule Set Category (1 of 2)

You can create new rule set categories. This is recommended only in the uncommon situation of an implementation that needs a new type of rule set category that is completely unlike any existing rule set category, however. To create a new rule set category, right-click the Rule Sets node and select New > Rule Set Category. You can also create a rule set category as a child node of an existing rule set category if there is a need to subgroup rule sets.

Hierarchy: Rule Set Category (1 of 2)

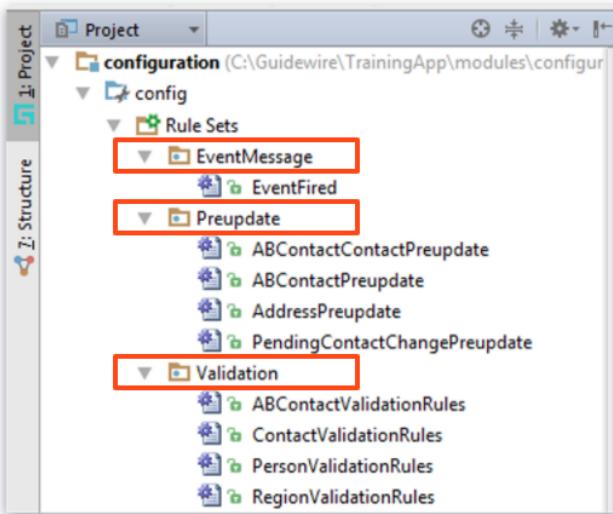

- A **Rule Set Category** is a collection of Rule Sets that have the following 2 things in common:
 - High-level business purpose
 - Trigger (Event)

Hierarchy: Rule Set Category (2 of 2)

Guidewire applications contain the triggers for event messaging, preupdate, and validation. These triggers are associated with their respective rule set categories. This is true of all Guidewire applications and not just TrainingApp. If you create a new rule set category, you must also write the code necessary to trigger the rule sets in the rule set category. For more information, consult the Rules Guide in documentation.

Hierarchy: Rule Set Category (2 of 2)

In Project View, the top-level node is Rule Sets, a misnomer. The physical folder is ...\\config\\rules\\.

- Examples:

- EventMessage

- Performs event processing and generates messages about events that have occurred

- Triggered during save

- Preupdate

- Performs domain logic or validation that must come before committing entity

- Triggered during save

- Validation

- Performs validation that must come before committing entity that ensures data is valid

- Triggered during save

Hierarchy: Rule Sets

You can think of a rule set as a logical grouping of rules that are specific to a business function. You organize the rules in a rule set into a hierarchy that fits your business model. In other words, a rule set combines many individual rules into a useful set to consider as a group. One way that Guidewire helps you define the organization of rules is with a root entity and common triggers. A rule set is a collection of rules that share the same root entity and share common triggers. You write code for new rule set categories to define the triggers associated with a rule set. If you create rule sets for an existing rule set category (Event Messaging, Pre-update, and Validation), you do not need write trigger code.

Execution of rules always occurs at the rule set level. Unless the rules engine encounters an exit() command, all rules in the rule set are executed.

TrainingApp is built by heavily customizing an instance of ContactManager, and therefore has the same rule sets as ContactManager. These include:

- The Event Fired rule set, which is associated with MessageContext and triggers when a MessageContext object fires an integration event

Hierarchy: Rule Sets

ABContact Preupdate (Active)

Description

This is the ABContact Preupdate rule set to permit modification of the contact and related entities. Exceptions will cause the bounding database transaction to roll back, effectively vetoing the update.

Root Entity
entity.ABContact

- A **Rule Set** combines many individual rules into a useful set to consider as a group
- A **Rule Set** defines the root entity type
 - All the Rules in the set will be attached to same the triggering entity (root entity)
- Only the Rule Set Editor exposes individual rules.

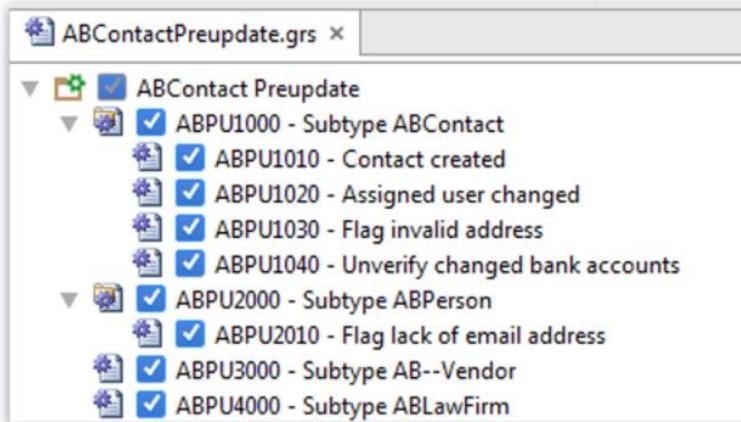

Hierarchy: Rules

If a rule has child rules, but the parent rule condition is false, neither the parent action nor the child rules are executed. In the slide example, the active (checked check box) rules are executed in the following hierarchy:

- ABPU1000 gathers together the rules relevant for all contacts. The child rules are executed only if this condition is true.
 - ABPU1010 creates a new history event when a contact is created.
 - ABPU1020 executes the necessary actions when a contact's assigned user changes (such as creating a note to record the change).
 - ABPU1030 executes the necessary actions when a flagged contact is unflagged (such as creating a note to record who unflagged the contact).
- ABPU2000 checks to see if the contact is an ABPerson. The child rules are executed only if this condition is true.
 - ABPU2010 flags any person who does not have an email address.

Hierarchy: Rules

- A **Gosu Rule** consists of a root entity, an expression that resolves to true or false, and an action that is executed if the condition is true
- Rules can have child rules
- If parent condition is true, Guidewire executes action and then executes all child rules

What is the significance of a rule set's root entity?

Answer

What is the significance of a rule set's root entity?

Every rule set is tied to an entity, known as the root entity. This determines which class of objects the rule set is tied to. It also determines the object available to the rules in the rule set when the rule set is triggered.

Page 3

[◀ PREV](#) [NEXT ▶](#)

Gosu enhancements

Guidewire types that can be enhanced include entities, Java classes, permissions, and SOAP entities. A fundamental reason for enhancing an entity is to add behaviors to a type that would not be appropriate to do by creating a subtype.

Gosu enhancements

- Gosu enhancements allow you to augment classes and other types with additional concrete methods and properties
- The most valuable and useful uses of this feature are:
 - to add new properties and methods to Guidewire Entities. Entities are defined in XML files and source code is automatically generated, thus cannot be modified, and
 - to define additional utility methods on a Java class or interface that cannot be directly modified. For example, the source code is unavailable, or a given class is final (cannot be subclassed)
- If an Entity/Java class is enhanced, then all the subtypes/subclasses will automatically inherit all elements from the enhancement

Guidewire Proprietary & Confidential – DO NOT DISTRIBUTE
© 2021 Guidewire Software, Inc. For information about Guidewire's trademarks, visit <https://www.guidewire.com/legal-notices>.

Page 4

Enhancement components

Enhancements can have any number of the following: getters, setters, and methods.

Enhancement components

Getter properties

- Calculate derived values

Setter properties

- Take input parameters, and/or

Functions

- Set field values that require additional logic
- Modify other objects, and/or
- Create objects

Derived (virtual) properties

In the slide example, ABPersonEnhancement.gsx is the enhancement file that extends the ABPerson entity with an Age property.

Derived (virtual) properties

- ABPersonEnhancement.gsx enhances ABPerson entity and defines the Age getter property
- Property calculates age based on the date of birth value
- Derived values should NOT be stored in the database, because storing them would be redundant
 - They are calculated from physical fields

Person Info		Phone & Addresses	Bank Accounts	Employment Info	
Name				Occupation	Employer
Full Name	William Andy				Albertson's
Prefix					
First Name	William				
Middle Name					
Last Name	Andy				
Suffix					
Tax Info				Personal Statistics	
Tax ID	*****			Height	40
Tax Filing Status	Single			Age	39
Gender	Male				
Marital Status	Single			Contact Insights	
Date of Birth	08/02/1979			Insight Score	0

Getter property

A getter is appropriate when you can derive a value and the derived value does not need to be stored in the database. In the slide example, ABPersonEnhancement.gsx is the enhancement file that extends the ABPerson entity with an Age property.

Getter property

- A **getter property** is used to calculate a derived value
 - Property not declared at Data Model level
 - As a result the value is not stored in database
 - Code cannot receive input parameters
 - Code can only return a value and should not alter any data
 - Null safe
 - Example: **ABPerson . Age**
 - Derives value by calculating number of years between date of birth and current date
 - Returns "Unknown" if date of birth is null
 - Storing Age in database is redundant

Setter property

An implementation of any Guidewire application will have a small number of setters because of the limiting criteria for use. A setter is appropriate only when you need to set one or more fields based on a single input value and—if there is a single field to be set—it is a field that cannot be set by simply assigning the input value to the field.

Possible use cases for setters could include:

- Adding a value to one field out of several possible fields (such as adding a new phone number to either Work Phone, Home Phone, or Cell Phone).
- Adding an object to an array and making that value the primary object (such as adding a new employee to an ABCCompany and making that employee the primary contact).
- Adding a value to a field that must be converted to a different unit (such as receiving a dollar amount in Euros but needing to store that amount as dollars).
- Converting an integer value to a typekey value (such as receiving an integer that represents the number of employees and using that to set a CompanySize typekey value which could be: Under 100, 101 to 500, ...)

Setter property

- A **setter property** takes a single input value and uses it to modify the associated object
 - Property not declared at data model level
 - Value given to setter may or may not be stored in database
 - Value manipulated by setter is typically stored in database
 - Code must receive exactly one input parameter
 - Should not be used to alter other objects
- Example: **ABPolicyPerson.HeightInInches (arg)**
 - Getter takes height from database (in meters) and converts it to inches (so, for example, it can be displayed in UI)
 - Setter takes height (in inches) and converts it to meters before saving it to database

Page 8

[◀ PREV](#) [NEXT ▶](#)

Gosu enhancements provide additional methods (functionality) on a Guidewire entity. For example, suppose that you create an enhancement to the Activity entity. Within this enhancement, you add methods that support new functionality. Then, if you type Activity. (Activity dot) within any Gosu code, Studio automatically uses code completion on the Activity entity. It also automatically displays any methods that you have defined in your Activity enhancement, along with the native Activity entity methods.

Gosu enhancements for Java

- Write Gosu enhancements for Java types
- Useful when creating generic methods that...
 - Do NOT relate to a specific entity
 - Extend the functionality of a base data type
- Examples:
 - GWBaseIntegerEnhancement enhances `java.lang.Integer`
 - GWBaseDateEnhancement enhances `java.util.Date`
 - GWBaseListEnhancement enhances `java.util.List`
- Java enhancements typically contain static functions
- Deploy and debug the same way as other enhancements

What type of logic does a getter implement? A setter? A method?

Answer

-- What type of logic does a getter implement? A setter? A method?

The correct responses are:

Getter: Logic that returns a derived value and does not take parameters or change other data.

Setter: Logic that takes a single input value and uses that to modify some other field or set of fields on the given object.

Method: Logic that requires parameters, changes data, or otherwise does more than simply deriving or setting a value.

Page 4

[◀ PREV](#) [NEXT ▶](#)

Pattern matching

Validation is a general application behavior that prevents a user from saving invalid business data. Field-level validation is a validation behavior tied to one or more specific data fields.

A regular expression defines a pattern. The save is not allowed if the data entered by the user doesn't match the pattern.

Input masks both display a watermark in the field and guide the user to input the correct format of data. An input mask does not restrict data commit, but it does guide the user to input the data in a certain format.

Pattern matching

- Pattern matching is a field-level validation technique
- Verifies that the user entered the data in the correct format for that field
 - E.g.: tax id must be a nine-digit number with hyphens after the third and fifth digits
 - Prevents the user from saving invalid business data
- Could be implemented in the data model or the UI tier
- Main components:
 - Regular expression
 - Input mask (optional)

Pattern matching - regular expressions

The pattern for the Email validator is:

- Any non-empty string, specified as: .+
- An "at" symbol, specified as: @
- Any non-empty string, specified as: .+
- A period, specified as: \.
- Any non-empty string, specified as: .+

Characters that are not treated as literals and must be escaped include: [] () {} . * + ?

For a complete listing of syntax for validator patterns, consult the Configuration Guide for your product.

Pattern matching - regular expressions

- A regular expression defines an abstract pattern
- Examples:
 - Email address: .+@.+\.\.+
 - Routing number: [0-9a-zA-Z]{3}-[0-9]{3}

Details

Validation errors on current page:

Routing Number : Must be 3 alphanumerics, a hyphen, and 3 digits.

Person Info	Phone & Addresses	Bank Accounts	Financial Summary

◀ PREV NEXT ▶

Pattern matching – input masks

Input masks and regular expressions guide the user input for the field. Client-side regular expressions notify the user of an issue with the field input when a placeholder character (#) is used in the inputMask expression. An input mask identifies to the user the specific form of the data to enter into a given field. Typically, an input mask shows a basic pattern for a field. Input masks can also guide the user to input a specific character input in the field.

When an input mask contains placeholders (e.g., #) but does not specify either a regex property or does not have an associated entity field validator, the framework generates an implicit regular expression based on the inputMask property definition. As the user types in the field, the implicit regex triggers client-side validation, but does not restrict data commit. Instead, it guides the user to input the data in a certain format. In the example above, the field value should be 5 characters in length, the first two being upper case letters and the last three being numbers.

It should be noted that in addition to placeholders (#) in an inputMask property expression, you can force certain characters to be in the data. For example, "AB ###" forces the field to have the upper-case letters A and B to be the first two characters in the entry.

Pattern matching – input masks

- Appears as a watermark in field and mouse over tooltip
 - Changes to a darker color with data entry
 - No format warning
 - Does not restrict data commit but instead guides the user to input the data in a certain format

The screenshot illustrates the configuration and usage of input masks. At the top, a configuration panel shows the following properties:

inputMask	##-###
inputConversion	"##-##"
inputMask	"##-##"
labelAbove	False

Below this, two examples demonstrate the input mask's effect:

- Example 1:** A field labeled "License" contains "BB-BBB". A red arrow points to the placeholder character "B" in the input field, which is highlighted in green, indicating it is a placeholder.
- Example 2:** A field labeled "License" contains "AB-123". A red arrow points to the placeholder character "A" in the input field, which is highlighted in green, indicating it is a placeholder.

At the bottom, a validation error message is displayed:

Validation errors on current page:
1 License : The value in this field is invalid

Pattern matching- practices comparison

Shown here are the pros and cons and pattern matching in the Data Model and the User Interface.

Pattern matching- practices comparison

Data model

- Pros
 - Application enforces compliance in the UI and through API
 - Supports full localization
 - Robust extensibility
- Cons
 - Static values only: regex and input mask cannot change based on business logic
 - Implemented as a reusable field validator

User interface

- Pros
 - Dynamic values: regex and input mask can change based on business logic
 - Can restrict data commit
- Cons
 - Only a few widget support it
 - Must be configured per widget
 - No custom error message option
 - Extensibility a big concern
- Implemented as widget properties

Page 8

Example: pattern matching in the UI

PCF Format Reference:
<application-installation-folder>/modulespcf.html

Example: pattern matching in the UI

- Implementing the user story in the UI requires duplicating regex and input mask
- **inputMask** and **regex** properties can be dynamic
 - To improve the design, a function call could be used instead of hard-coding the strings
- No custom error message
- Not all the widgets have the **regex** and **inputMask** properties
 - Refer to PCF Format Reference

Property	Value
inputMask	"##-#####"
labelStyleClass	false
maxChars	0
numCols	-1
numEntriesPerColumn	0
gnPick	
outputConversion	
printWidth	1
regex	"[A-Z]{2}-[0-9]{7}"

Page 9

Script parameters

- A **script parameter** is an application-wide global constant
 - Value maintained by administrator
 - Can be referenced in any Gosu code
 - Typically used for values that may change over time and therefore should not be hard-coded

The screenshot shows a user interface with two main sections: 'Additional Info' on the left and a modal window titled 'Details' on the right.

Additional Info:

- Tax ID: *****
- Inspection Required?: No
- Preferred Currency: <none selected>
- Collateral Info:**
- Collateral Required?: Yes
- Collateral Amount: 4000
- Collateral Verified?: <none selected>

Details Modal:

Collateral Amount : Collateral must be at least 5000

Update Cancel

Red boxes highlight the 'Collateral Amount' field (containing '4000') and the validation message in the 'Details' modal (containing 'Collateral must be at least 5000'). Red arrows point from these highlighted areas to the corresponding text in the list below.

Examples from base applications

Script Parameters		BillingCenter	
Name ↑		Script Parameters	
InitialReserve_AutoGlassVehicleDamage	java.lang.Integer	ClaimCenter	
LegacyAgencyBillPlan	java.lang.Object	InitialReserve_AutoMajorVehicleDamag...	java.lang.Integer 500

[◀ PREV](#) [NEXT ▶](#)

Partial page update: Layout re-render

In the slide example, the Company Info card has both an Inspection Required field and Inspection Date field. However, the Inspection Date field is visible only if the Inspection Required? field is set to Yes.

The InspectionRequired widget displays a Yes or No radial buttons. A selected Yes radial button equates to true and a selected No radial button equates to false. A null value is represented as neither radial button selected.

Dynamic widget behavior differs from a property that evaluates an expression in that the user changes the business data while editing it and that change affects the behavior of the widget. In the previous examples, the changes are present only after the data has been committed.

Partial page update: Layout re-render

- Responds to a user changing business data **while** it happens and changes the layout of widgets on the screen
- Example:
 - While a user changes the Did agent inspect vehicles? field to Yes, a secondary question and the Date Input widget becomes visible

The screenshot shows two states of a 'Qualification' form. In the first state, the 'Did agent inspect vehicles?' field has a 'No' radio button selected. In the second state, the 'Yes' radio button is selected, and a red arrow points from this change to the 'When was the inspection?' field, which is now displayed and contains a date input field ('MM/dd/yyyy').

Page 10

◀ PREV NEXT ▶

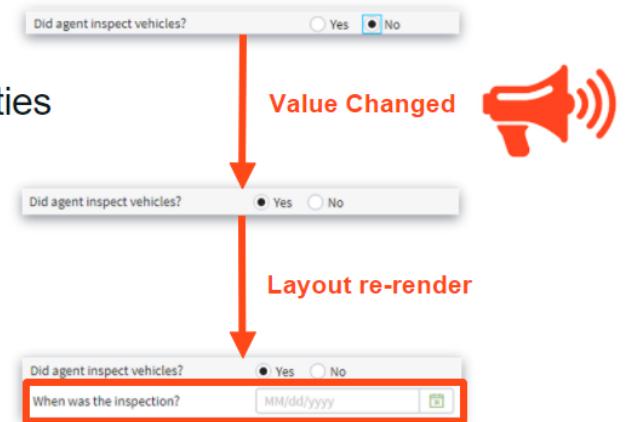

Partial page update: Layout re-render (Continued)

There are two general and non-exclusive categories for a partial page update: layout re-render and DATA_ONLY.

In the layout re-render example above, whenever the value of the InspectionRequired field is changed, all user editable data is sent from the client to the application server. No data is committed. The application server processes the request and returns instructions and user editable data to the client. The client re-renders the layout that shows an Inspection Date field.

Partial page update: Layout re-render (Continued)

- Layout re-rendered for the page
- No data committed
- Applies to following dynamic widget properties
 - visible
 - editable
 - available
 - required

Partial page update: DATA_ONLY

In the DATA_ONLY example, the widget configuration enables dynamic widget behavior for the Affinity Group name TextInput widget. When a user changes the value of the Name field, the client makes a request to the application server. The application server processes the request and returns instructions to the client. In this case, the instructions tell the client to render only the newly supplied data for the Business and Operations fields (year started and description of business).

Partial page update: DATA_ONLY

- Responds to a user changing business data **while** it happens
 - Not after the user navigates to the page
 - Not after the user commits or tries to commit the data
- Example:
 - While a user changes the Affinity Group Name field, values for other fields are rendered with changes (read-only in UI)

The figure consists of two side-by-side screenshots of a business form. Both screenshots show the same set of fields: County (San Mateo), Address Type (Home), Address Description (Created by the Address Builder with code 0), Official IDs (SSN: 342-56-8729, Industry Code: 0740), Business and Operations (Year Business Started: 1967, Description of business and operations: 'business description'), and Underwriting Companies (Acme Low Hazard Insurance). In the top screenshot, the 'Base State' dropdown is set to 'California'. In the bottom screenshot, the 'Base State' dropdown has been changed to 'Arizona'. Additionally, the 'Affinity Group' field has been updated to 'Bellingham'. Red arrows point from the text 'Base State' to the dropdown in both screenshots, and another red arrow points from the text 'Affinity Group' to its corresponding field in the bottom screenshot.

Two kinds of widget properties

In the slide example, the id property of a widget is a static property. The widget always has the same ID, regardless of the state of the application or the values of any business data. The property does not evaluate an expression, just the value of a type, such as a String or Integer value.

The editable property evaluates a boolean expression and the expression can be a dynamic value, in this case, one that returns true or false. The label property evaluates a string expression. This lesson discusses display keys later on. Display keys are a type of string expression Guidewire applications for localizing text. The value property is also a dynamic property. The value property evaluates an object expression that binds the object property to it.

Both types of widget properties can be required properties for a specific type of widget.

Two kinds of widget properties

Static Property

- Evaluates a static value that is immutable, never changes
 - id requires a static value

Dynamic Property

- After a user navigates to a page or clicks update, evaluates an expression and returns a value
 - editable requires boolean expression
 - label returns a string expression
 - value returns an object expression

Property	Value
editable	true
id*	FirstName
label	DisplayKey.get("Training.FirstName")
required	
value*	(anABCContact as ABPerson).FirstName

Page 4

[PREV](#) [NEXT](#)

Dynamic properties evaluate expressions

Not all widgets have all properties. Refer to the PCF Format Reference for more examples. Recall that the PCF Format Reference defines the properties for every widget, including the type of value the property takes. Note that the PCF Format Reference refers to widget properties as "attributes". To open the PCF Format Reference, open <ApplicationRootDirectory>\modules\pcf.htm file in your web browser.

You can also consider the value property of a widget to be a dynamic property because it evaluates an object expression.

Visible is typically not set to false. It is either set to true or it is set to an expression that renders the widget visible or not visible. The default value for the visible property is true.

Dynamic properties evaluate expressions

- Available
 - Boolean expression which, if false, grays out the widget and its children
- Editable
 - Boolean expression which, if false, makes the widget and its children read-only
- Required
 - Boolean expression which, if true, then a value must be filled out by the user
- Visible
 - Boolean expression which, if false, completely hides the widget and its children

Notes

Post On Change properties

In certain cases, you may want to toggle (disable or enable) targeted Post On Change behavior for a specific widget.

In the slide example, the Invoicing Method field will disable Post On Change if the currency is not USD.

For all other currencies, the Post On Change will be disabled. The widget will not announce a change in its value; data will not make a round-trip between client and the application server; the page will not be re-rendered and data won't be refreshed.

In the slide example, the Gosu expression defined for the onChange property invokes the setFieldsOnResolution() function. The function is defined in the entity enhancement, FlagEntryEnhancement.gsx.

```
16 /* This function is called when
a FlagEntry's resolution field
17 is set. This function sets the
UnflagDate and UnflagUser
18 fields. This serves the role of a
"FlagEntry Pre-Update"
19 rule set.
20 */
21 function
setFieldsOnResolution(): void {
22 this.UnflagDate =
gw.api.util.DateUtil.currentTimeMillis()
23 this.UnflagUser =
User.util.getCurrentUser()
24 } // end of function
```

Post On Change properties

disablePostOnEnter

- If evaluated true when page is rendered, this field won't trigger Post On Change
- Default is false

Invoicing Method aPolicy.InvoicingMethod ▾

Page Configuration Text

PostOnChange

disablePostOnEnter aPolicy.Premium_cur != Currency.TC_USD
onChange

onChange

- Defines a Gosu expression to invoke when user changes the value of the widget
- Causes immediate post back to the server

Resolution aFlagEntry.Resolution

Page Configuration Text

Properties: Properties Layout config Reflection PostOnChange

Enable targeted Post On Change

PostOnChange

onChange aFlagEntry.setFieldsOnResolution()

Target property (earlier versions)

When specified as a widget, the target area can be a specific widget or a grouping of widgets. For example, if the Widget ID corresponds to an Input Set, then the widgets in the input set are re-rendered.

There is an additional layout re-render configuration for backwards compatibility: no value. The no value configuration consists of enabling targeted post on change alone with no property configurations. The backwards compatibility configuration has no property values specified and causes the re-rendering of the entire page and refreshes all user-editable data. There is a high-performance cost for implementing targeted Post On Change without specifying a target and any other properties.

In current InsuranceSuite applications, targeted update is automatic for any widget where Targeted Post On Change is enabled, and the target property is redundant.

Target property (earlier versions)

Layout re-render

- Widget ID
- Target area re-rendered
- All editable data refreshed
- Widgets can also be grouped and parent container can be targeted

Data update

- DATA_ONLY
- No layout re-render
- All editable data refreshed
- Better performance

Page 16

Answer

-- Name two properties that evaluate expressions.

Possible answers include:

- editable
- required
- visible
- available

How is a partial page update implemented?

Answer

-- How is a partial page update implemented?

A partial page update is implemented by configuring dynamic widget behavior by enabling targeted post on change. Often the dynamic widget behavior configuration also includes configuring an expression for a widget property.
